## 1 Introduction

In this lecture, we show how to construct a public-key encryption scheme secure against non-adaptive chosen-ciphertext attacks, given a semantically-secure public-key encryption scheme and an adaptively-secure non-interactive zero-knowledge proof system (in the common random string model).

## 2 Adaptively-Secure Non-Interactive Zero-Knowledge

We begin with a definition of a basic case of non-interactive zero-knowledge.

**Definition 1** A pair of PPT algorithms  $(\mathcal{P}, \mathcal{V})$  is a non-interactive zero-knowledge (NIZK) proof system for a language  $L \in NP$  if there exists some polynomial poly such that:

1. Completeness (for  $x \in L$ ,  $\mathcal{P}$  generates proofs that  $\mathcal{V}$  accepts): For all  $x \in L \cap \{0,1\}^k$  and all witnesses w for x,

$$\Pr[r \leftarrow \{0,1\}^{\operatorname{poly}(k)}; \Pi \leftarrow \mathcal{P}(r,x,w) : \mathcal{V}(r,x,\Pi) = 1] = 1.$$

2. Soundness (for  $x \notin L$ , no prover can generate proofs that  $\mathcal{V}$  accepts with better than negligible probability): For all  $x \in \{0,1\}^k \setminus L$  and all (possibly unbounded) algorithms  $\mathcal{P}^*$ , the following is negligible in k:

$$\Pr[r \leftarrow \{0, 1\}^{\operatorname{poly}(k)}; \Pi \leftarrow \mathcal{P}^*(r, x) : \mathcal{V}(r, x, \Pi) = 1].$$

3. Zero-knowledge (for  $x \in L$ , the view of any verifier can be efficiently simulated without knowledge of a witness): There exists a PPT algorithm Sim such that for any  $x \in L \cap \{0,1\}^k$  and any witness w for x, the following ensembles are computationally indistinguishable:

(1) 
$$\begin{cases} r \leftarrow \{0,1\}^{\operatorname{poly}(k)} ; \Pi \leftarrow \mathcal{P}(r,x,w) : (r,x,\Pi) \end{cases}_{k} \\ (2) \quad \{(r,\Pi) \leftarrow \operatorname{Sim}(x) : (r,x,\Pi) \}_{k} . \end{cases}$$

 $\diamond$ 

For our purposes, we need to strengthen the definition in two ways. In the soundness requirement, we would like to also protect against a prover who chooses  $x \notin L$  after seeing the common random string r. In the zero-knowledge requirement, we would like to make the simulator's job a little harder by making it output a simulated common random string

r first, and only then supplying it with an  $x \in L$  for which it needs to generate a simulated proof. In particular, such an x may be chosen adaptively (by an adversary, say) based on r. In the following, we use  $\Pr_{\mathsf{E}}[\mathsf{A}]$  to denote the probability that event A occurs in the probabilistic experiment E.

**Definition 2** A pair of PPT algorithms  $(\mathcal{P}, \mathcal{V})$  is an *adaptive, non-interactive zero-knowledge*  $(aNIZK^1)$  proof system for a language  $L \in NP$  if there exists a polynomial poly such that:

- 1. Completeness: Same as above.
- 2. Soundness (now, the cheating prover may choose  $x \notin L$  after seeing r): For all (possibly unbounded) algorithms  $\mathcal{P}^*$ , the following is negligible in k:

$$\Pr\left[r \leftarrow \{0,1\}^{\operatorname{poly}(k)}; (x,\Pi) \leftarrow \mathcal{P}^*(r): \mathcal{V}(r,x,\Pi) = 1 \land x \in \{0,1\}^k \setminus L\right].$$

3. Zero-knowledge (simulator must output r first, is then given x, and asked to produce a simulated proof): Let  $(Sim_1, Sim_2)$ ,  $(A_1, A_2)$  be a pair of two-staged algorithms (we may assume that the first stage outputs some state information which is passed as input to the second stage; this will be implicit). Consider the following experiments:

$$\begin{array}{ll} \operatorname{Game} \mathsf{ZK}_{\operatorname{real}} & \operatorname{Game} \mathsf{ZK}_{\operatorname{sim}} \\ r \leftarrow \{0,1\}^{\operatorname{poly}(k)} & \\ (x,w) \leftarrow A_1(r) & (x \in L \cap \{0,1\}^k) \\ \Pi \leftarrow \mathcal{P}(r,x,w) & \\ b \leftarrow A_2(r,x,\Pi) & \\ \end{array} \begin{array}{l} \operatorname{Game} \mathsf{ZK}_{\operatorname{sim}} \\ r \leftarrow \operatorname{Sim}_1(1^k) \\ (x,w) \leftarrow A_1(r) & (x \in L \cap \{0,1\}^k) \\ \Pi \leftarrow \operatorname{Sim}_2(x) \\ b \leftarrow A_2(r,x,\Pi) & \\ \end{array} \right.$$

We require that there exist a PPT simulator  $(Sim_1, Sim_2)$  such that for any PPT algorithm  $(A_1, A_2)$  the following is negligible in k:

 $|\Pr_{\mathsf{ZK}_{real}}[A_2 \text{ outputs } 0] - \Pr_{\mathsf{ZK}_{sim}}[A_2 \text{ outputs } 0]|.$ 

Equivalently, the "real" game  $ZK_{real}$  is computationally indistinguishable from the "simulated" game  $ZK_{sim}$ . (In other words, the adversary cannot tell whether it is participating in the first or the second experiment (except with negligible probability).  $A_2$ 's output can be thought of as its guess towards which experiment it is in. This means that the simulator is able to simulate the adversary's view in the real execution.)

 $\diamond$ 

To simplify the notation a little, we will usually drop the stage identifier for A; when we refer to A's output in the experiment, we will mean  $A_2$ 's output.

## 3 A Public-Key Encryption Scheme Secure Against Non-Adaptive Chosen-Ciphertext Attacks

Let  $(Gen, \mathcal{E}, \mathcal{D})$  be a public-key encryption scheme and  $(\mathcal{P}, \mathcal{V})$  be an adaptively-secure NIZK proof system for languages in NP. The following construction is due to Naor and Yung [1].

<sup>&</sup>lt;sup>1</sup>This notation is non-standard.

$$\begin{array}{c|c} \underline{\mathsf{Gen}^{*}(1^{k})}{(pk_{1},sk_{1})} \leftarrow \underline{\mathsf{Gen}}(1^{k});\\ (pk_{2},sk_{2}) \leftarrow \underline{\mathsf{Gen}}(1^{k});\\ r \leftarrow \{0,1\}^{\mathrm{poly}(k)};\\ pk^{*} = (pk_{1},pk_{2},r);\\ sk^{*} = sk_{1} \end{array} \qquad \qquad \begin{array}{c|c} \underline{\mathcal{E}}^{*}_{(pk_{1},pk_{2},r)}(m) \\ \overline{w_{1},w_{2}} \leftarrow \{0,1\}^{*};\\ c_{1} = \underline{\mathcal{E}}_{pk_{1}}(m;w_{1});\\ c_{2} = \underline{\mathcal{E}}_{pk_{2}}(m;w_{2});\\ \Pi \leftarrow \mathcal{P}(r,(c_{1},c_{2}),(w_{1},w_{2},m));\\ \mathrm{Output}\ (c_{1},c_{2},\Pi) \end{array} \qquad \qquad \begin{array}{c|c} \underline{\mathcal{D}}^{*}_{sk_{1}}(c_{1},c_{2},\Pi) \\ \overline{\mathsf{If}}\ \overline{\mathcal{V}}(r,(c_{1},c_{2}),\Pi) = 0\\ \mathrm{Output}\ \bot;\\ \mathrm{else}\\ \mathrm{Output}\ \mathcal{D}_{sk_{1}}(c_{1}) \end{array}$$

A few words of explanation are due here. For key generation, we use the underlying key-generation algorithm to produce two pairs of (public, private) keys, publish the public keys and a random string r (to serve as the common random string for the proof system), and keep the first underlying private key as our private key (we discard the second private key). For encryption, we use the underlying algorithm to encrypt the given message m twice, under both  $pk_1$  and  $pk_2$ , with the random tapes of the encryption algorithm fixed to  $w_1, w_2$ , respectively.<sup>2</sup> (For a probabilistic algorithm  $A(\cdot)$ , the notation  $A(\cdot; w)$  is used to denote that A's random tape is fixed to a particular  $w \in \{0,1\}^*$ .) We then use our prover to generate a proof that  $(c_1, c_2)$  are encryptions of the same message under  $pk_1, pk_2$  in the underlying scheme; i.e.,  $(c_1, c_2) \in L$  where

$$L = \{(c_1, c_2) | \exists m, w_1, w_2 \text{ such that } c_1 = \mathcal{E}_{pk_1}(m; w_1), c_2 = \mathcal{E}_{pk_2}(m; w_2) \},\$$

using  $w_1, w_2$ , and m as witnesses. Note that  $L \in NP$ . We send the ciphertexts and the proof to the receiver. For decryption, we use the underlying decryption algorithm on the first ciphertext, if the provided proof verifies correctly.

**Theorem 1** Assuming that  $(\text{Gen}, \mathcal{E}, \mathcal{D})$  is semantically secure and that  $(\mathcal{P}, \mathcal{V})$  is an adaptivelysecure NIZK proof system,  $(\text{Gen}^*, \mathcal{E}^*, \mathcal{D}^*)$  is secure against non-adaptive ("lunchtime"<sup>3</sup>) chosen-ciphertext attacks (i.e., is CCA1 secure).

The remainder of these notes is the beginning of a proof of this theorem (we continue the proof next lecture). Let A be a two-staged PPT algorithm, where the first stage has access to an oracle. Consider the following two experiments (their differences are in boldface):

| Game $CCA1_0$   | Game $CCA1_1$  |
|---|--|
| $(pk_1, sk_1), (pk_2, sk_2) \leftarrow Gen(1^k)$  | $(pk_1, sk_1), (pk_2, sk_2) \leftarrow Gen(1^k)$   |
| $r \leftarrow \{0,1\}^{\operatorname{poly}(k)}$   | $r \leftarrow \{0, 1\}^{\operatorname{poly}(k)}$   |
| $pk^* = (pk_1, pk_2, r), \ sk^* = sk_1$   | $pk^* = (pk_1, pk_2, r), \ sk^* = sk_1$  |
| $(m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*)$                                       | $(m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*)$                                      |
| $w_1, w_2 \leftarrow \{0, 1\}^*$  | $w_1, w_2 \leftarrow \{0, 1\}^*$   |
| $c_1 = \mathcal{E}_{pk_1}(\boldsymbol{m_0}; w_1),  c_2 = \mathcal{E}_{pk_2}(\boldsymbol{m_0}; w_2)$ | $c_1 = \mathcal{E}_{pk_1}(\boldsymbol{m_1}; w_1), c_2 = \mathcal{E}_{pk_2}(\boldsymbol{m_1}; w_2)$ |
| $\Pi \leftarrow \mathcal{P}(r, (c_1, c_2), (w_1, w_2, \boldsymbol{m_0}))$                           | $\Pi \leftarrow \mathcal{P}(r, (c_1, c_2), (w_1, w_2, \boldsymbol{m_1}))$                          |
| $b \leftarrow A(pk^*, c_1, c_2, \Pi)$   | $b \leftarrow A(pk^*, c_1, c_2, \Pi)$  |

To prove the scheme CCA1 secure, we need to show that A cannot distinguish the above two games; i.e., to show that the following is negligible:  $|\Pr_{\mathsf{CCA1}_0}[b=0] - \Pr_{\mathsf{CCA1}_1}[b=0]|$ .

<sup>&</sup>lt;sup>2</sup>The notation  $w_1 \leftarrow \{0,1\}^*$  just means that a "long enough" random string is chosen.

 $<sup>^{3}</sup>$ That is, the adversary is assumed to be able to "play" with the decryption oracle while people are out for lunch, but not afterward when he gets the challenge ciphertext.

To that effect, we introduce a sequence of intermediate games, and show that A cannot distinguish each game from its subsequent one; the theorem will then follow.

Let  $Sim = (Sim_1, Sim_2)$  be the simulator for our proof system. In the first game, we replace the random string and legitimate proof of game  $CCA1_0$  with a simulated random string and simulated proof. Once again, the differences between the new game and game  $CCA1_0$  are highlighted.

Game 1  

$$(pk_1, sk_1), (pk_2, sk_2) \leftarrow \text{Gen}(1^k)$$
  
 $r \leftarrow \text{Sim}_1(1^k)$   
 $pk^* = (pk_1, pk_2, r), sk^* = sk_1$   
 $(m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*)$   
 $w_1, w_2 \leftarrow \{0, 1\}^*$   
 $c_1 = \mathcal{E}_{pk_1}(m_0; w_1), c_2 = \mathcal{E}_{pk_2}(m_0; w_2)$   
 $\Pi \leftarrow \text{Sim}_2((c_1, c_2))$   
 $b \leftarrow A(pk^*, c_1, c_2, \Pi)$ 

Claim 2  $|\Pr_{CCA1_0}[A \text{ outputs } 0] - \Pr_1[A \text{ outputs } 0]|$  is negligible.

**Proof** By reduction to the zero-knowledge property of the proof system: we use A to construct an algorithm B that attempts to distinguish real from simulated proofs.

$$\begin{split} B(1^k) \\ & \text{Receive } r \text{ as first-stage input;} \\ & (pk_1, sk_1), (pk_2, sk_2) \leftarrow \text{Gen}(1^k); \\ & pk^* = (pk_1, pk_2, r); \\ & sk^* = sk_1; \\ & (m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*); \, // \text{ note that } B \text{ has no trouble} \\ & // \text{ simulating the decryption oracle for } A \\ & w_1, w_2 \leftarrow \{0, 1\}^*; \\ & c_1 = \mathcal{E}_{pk_1}(m_0; w_1), \, c_2 = \mathcal{E}_{pk_2}(m_0; w_2); \\ & \text{Output } ((c_1, c_2), (w_1, w_2, m_0)) \text{ as first-stage output;} \\ & \text{Receive } \Pi \text{ as second-stage input;} \\ & b \leftarrow A(pk^*, c_1, c_2, \Pi); \\ & \text{Output } b \text{ as second-stage output.} \end{split}$$

Now, when the inputs to B are a random string r and a real proof  $\Pi$ , then A's view in the above experiment is precisely its view in game  $\mathsf{CCA1}_0$ , and so  $\Pr_{\mathsf{ZK}_{real}}[B \text{ outputs } 0] = \Pr_{\mathsf{CCA1}_0}[A \text{ outputs } 0]$ . On the other hand, when the inputs to B are a simulated string and a simulated proof, A's view in B is precisely its view in game 1, and so  $\Pr_{\mathsf{ZK}_{sim}}[B \text{ outputs } 0] = \Pr_1[A \text{ outputs } 0]$ . Since  $|\Pr_{\mathsf{ZK}_{real}}[B \text{ outputs } 0] - \Pr_{\mathsf{ZK}_{sim}}[B \text{ outputs } 0]|$  is negligible (since the proof system is adaptively-secure NIZK), we have that

$$|\Pr_{\mathsf{CCA1}_0}[A \text{ outputs } 0] - \Pr_1[A \text{ outputs } 0]|$$

is negligible as well.

The second game differs from game 1 in that it does not double-encrypt  $m_0$ , but instead encrypts  $m_0$  once and  $m_1$  once.

Game 2  

$$(pk_1, sk_1), (pk_2, sk_2) \leftarrow \text{Gen}(1^k)$$
  
 $r \leftarrow \text{Sim}_1(1^k)$   
 $pk^* = (pk_1, pk_2, r), sk^* = sk_1$   
 $(m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*)$   
 $w_1, w_2 \leftarrow \{0, 1\}^*$   
 $c_1 = \mathcal{E}_{pk_1}(m_0; w_1), c_2 = \mathcal{E}_{pk_2}(m_1; w_2)$   
 $\Pi \leftarrow \text{Sim}_2((c_1, c_2))$   
 $b \leftarrow A(pk^*, c_1, c_2, \Pi)$ 

Note that in the above, the simulator is given as input encryptions of two different messages. Such an input is not in L, and in general there is not much we can say about the simulator's output in this case. However, we will see that in this particular case the game is indistinguishable to A because the semantic security of the underlying encryption scheme implies that encryptions of  $m_0$  are indistinguishable from encryptions of  $m_1$ . Of course, this will require a formal proof.

**Claim 3**  $|\Pr_1[A \text{ outputs } 0] - \Pr_2[A \text{ outputs } 0]|$  is negligible.

**Proof** We use A to construct B that attempts to break the semantic security of the underlying scheme. Recall that B is given a public key, outputs two messages  $(m_0, m_1)$ , is given the encryption of one of these, and has to guess which one. But B does not have access to a decryption oracle.

```
\begin{split} B(pk) \\ &\text{Set } pk_2 = pk; \\ &(pk_1, sk_1) \leftarrow \mathsf{Gen}(1^k); \\ &r \leftarrow \mathsf{Sim}_1(1^k); \\ &pk^* = (pk_1, pk_2, r), \, sk^* = sk_1; \\ &(m_0, m_1) \leftarrow A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*); \, // \text{ note that } B \text{ has no trouble} \\ &// \text{ simulating the decryption oracle for } A \\ &\text{Output } (m_0, m_1); \\ &\text{Receive } c_2 \text{ (an encryption of either } m_0 \text{ or } m_1 \text{ using (unknown) random tape } w_2); \\ &w_1 \leftarrow \{0, 1\}^*; \\ &c_1 = \mathcal{E}_{pk_1}(m_0; w_1); \\ &\Pi \leftarrow \mathsf{Sim}_2((c_1, c_2)); \\ &b \leftarrow A(pk^*, c_1, c_2, \Pi); \\ &\text{Output } b. \end{split}
```

Now, when  $c_2$  is an encryption of  $m_0$ , then A's view above is precisely its view in game 1. On the other hand, when  $c_2$  is an encryption of  $m_1$ , then A's view above is precisely its view in game 2. Therefore, the probability that A distinguishes game 1 from game 2 is precisely the probability that B distinguishes an encryption of  $m_0$  from an encryption of  $m_1$ , which is negligible by the semantic security of the underlying encryption scheme.

In the same way as above, we would now like to "switch"  $c_1$  from being an encryption of  $m_0$  to being an encryption of  $m_1$ . Here, however, a potential problem arises! To prove a claim analogous to Claim 3, we would need to construct some adversary B that gets  $pk = pk_1$  and then has to distinguish whether the ciphertext  $c_1$  it receives is an encryption of  $m_0$  or  $m_1$ . But, in order to do this it has to somehow simulate a decryption oracle for A — and this seems to require  $sk_1$ , which B does not have! (If B has  $sk_1$  then it would be easy for B to break semantic security of the scheme...) So, we will have to do a little more work before continuing.

Let Fake be the event that A submits a query  $(c_1, c_2, \Pi)$  to its decryption oracle (in stage 1) such that  $\mathcal{D}_{sk_1}(c_1) \neq \mathcal{D}_{sk_2}(c_2)$  but  $\mathcal{V}(r, (c_1, c_2), \Pi) = 1$ . Note that  $\Pi$  is then a valid-looking proof for a false statement (since  $(c_1, c_2) \notin L$ ).

Claim 4  $Pr_2[Fake]$  is negligible.

**Proof** First, note that  $Pr_2[Fake] = Pr_1[Fake]$ . This is because A submits oracle queries only in its first stage, and up to that stage the games are *identical*.

Next, we show that  $|\Pr_1[\mathsf{Fake}] - \Pr_{\mathsf{CCA1}_0}[\mathsf{Fake}]|$  is negligible. Up to A's first stage, the games differ only in r being a random string or a simulated string. Construct an algorithm B that attempts to distinguish random from simulated strings, as follows:

$$\begin{split} B(r) & (pk_1, sk_1), (pk_2, sk_2) \leftarrow \mathsf{Gen}(1^k); \\ pk^* &= (pk_1, pk_2, r); \\ & \operatorname{Run} A^{\mathcal{D}^*_{sk^*}(\cdot)}(pk^*), \text{ simulating the oracle for } A \text{ normally except that} \\ & \text{ if for any decryption query } (c_1, c_2, \Pi) \text{ it is the case that} \\ & \mathcal{V}(r, (c_1, c_2), \Pi) = 1 \text{ but } \mathcal{D}_{sk_1}(c_1) \neq \mathcal{D}_{sk_2}(c_2), \\ & \text{ then output 1 and stop (note that now } B \text{ does not throw away } sk_2); \\ & \text{ Otherwise, once } A \text{ is done with its first stage simply output 0} \end{split}$$

Now,  $\Pr_{\mathsf{ZK}_{sim}}[B \text{ outputs } 0] = \Pr_1[\mathsf{Fake}]$ . Similarly,  $\Pr_{\mathsf{ZK}_{real}}[B \text{ outputs } 0] = \Pr_{\mathsf{CCA1}_0}[\mathsf{Fake}]$ . Since  $|\Pr_{\mathsf{ZK}_{real}}[B \text{ outputs } 0] - \Pr_{\mathsf{ZK}_{sim}}[B \text{ outputs } 0]|$  is negligible (since the proof system is adaptively-secure NIZK), we have that  $|\Pr_1[\mathsf{Fake}] - \Pr_{\mathsf{CCA1}_0}[\mathsf{Fake}]|$  is negligible as well.

Finally, note that  $\Pr_{\mathsf{CCA1}_0}[\mathsf{Fake}]$  is negligible. This is because  $\mathsf{Fake}$  occurs when A produces a valid proof for a  $(c_1, c_2) \notin L$ , which can only happen with a negligible probability because of the soundness of the NIZK proof system (note that r now is a truly random string). The claim follows.

We pick up the proof from here in the next lecture. Informally, the next game we introduce differs from game 2 only in that  $sk_2$  is used for decryption instead of  $sk_1$ . The adversary's view in the games only differs if Fake occurs, which happens with negligible probability. All that's left to be done is to switch  $c_1$  to an encryption of  $m_1$  (similar to the introduction of game 2), switch the decryption key back to  $sk_1$ , and then go back to a random string and a real proof (similar to the introduction of game 1). This gets us back to game CCA1 as desired, and will complete the proof.
