Announcements

- **Program #1**
  - Due Week from Friday

- **Reading**
  - Threads - Chapter 4 (ch 5, 6th Ed)
Process State Transitions

- **new**
- **ready**
- **running**
- **terminated**
- **waiting**

Transitions:
- **admitted**
- **interrupt**
- **dispatch**
- **I/O request or event wait done**
- **I/O request or event wait done**
- **Kill**
- **exit**
Components of a Process

- **Memory Segments**
  - Program - often called the text segment
  - Data - global variables
  - Stack - contains activation records

- **Processor Registers**
  - program counter - next instruction to execute
  - general purpose CPU registers
  - processor status word
    - results of compare operations
  - floating point registers
Process Control Block

- Stores all of the information about a process

- PCB contains
  - process state: new, ready, etc.
  - processor registers
  - Memory Management Information
    - page tables, and limit registers for segments
  - CPU scheduling information
    - process priority
    - pointers to process queues
  - Accounting information
    - time used (and limits)
    - files used
    - program owner
  - I/O status information
    - list of open files
    - pending I/O operations
Storing PCBs

- Need to keep track of the different processes in the system
- Collection of PCBs is called a process table
- How to store the process table?
- First Option:

<table>
<thead>
<tr>
<th></th>
<th>P1</th>
<th>P2</th>
<th>P2</th>
<th>P3</th>
<th>P4</th>
<th>P5</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Ready</td>
<td>Waiting</td>
<td>New</td>
<td>Term</td>
<td>Waiting</td>
<td>Ready</td>
</tr>
</tbody>
</table>

- Problems with Option 1:
  - hard to find processes
  - how to fairly select a process
Queues of Processes

- Store processes in queues based on state

![Diagram showing queues of processes](attachment:image.png)
forking a new process

- create a PCB for the new process
  - copy most entries from the parent
  - clear accounting fields
  - buffered pending I/O
  - allocate a pid (process id for the new process)

- allocate memory for it
  - could require copying all of the parents segments
  - however, text segment usually doesn’t change so that could be shared
  - might be able to use memory mapping hardware to help
    - will talk more about this in the memory management part of the class

- add it to the ready queue
Process Termination

- **Process can terminate self**
  - via the exit system call

- **One process can terminate another process**
  - use the kill system call
  - can any process kill any other process?
    - No, that would be bad.
    - Normally an ancestor can terminate a descendant

- **OS kernel can terminate a process**
  - exceeds resource limits
  - tries to perform an illegal operation

- **What if a parent terminates before the child**
  - called an orphan process
  - in UNIX becomes child of the root process
  - in VMS - causes all descendants to be killed
Termination (cont.) - UNIX example

- **Kernel**
  - frees memory used by the process
  - moved process control block to the terminated queue

- **Terminated process**
  - signals parent of its death (SIGCHILD)
  - is called a zombie in UNIX
  - remains around waiting to be reclaimed

- **parent process**
  - wait system call retrieves info about the dead process
    - exit status
    - accounting information
  - signal handler is generally called the reaper
    - since its job is to collect the dead processes
