Lecture 2
Introduction to Concurrency
Running a Sequential Program

- **Executable**
  *Machine instructions to be performed*

- **Program counter**
  *Next instruction to be executed*

- **Stack**
  *Current variable definitions*

- **Heap**
  *Dynamically allocated data structures*

- **Control flow**
  *Sequence of instructions performed during an execution*
Java Memory Model

• Stack
  – Local variables
  – Method parameters

• Heap
  – Objects!
  – Every call to `new` allocates space on heap

• Class-typed variables reference heap or null
More on Main Memory (MM)

• Naively, MM is a table:
  – Each address can store a value
  – Each address refers to one memory location (no copies)

• In reality, several copies of a given address are possible
  – Caches
  – Registers
  – …

• Why? *Performance*
  – Higher-speed memory is more expensive
  – Copying frequently used data into high-speed memory (register, cache) improves performance while containing cost

<table>
<thead>
<tr>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>‘a’</td>
</tr>
<tr>
<td>0001</td>
<td>37</td>
</tr>
<tr>
<td>0002</td>
<td>NULL</td>
</tr>
</tbody>
</table>
Concurrent Programs

• Multiple control flows!
• Programs with multiple control flows can be
  – Concurrent
  – Parallel
  – Distributed
• Control flows are either
  – Processes
  – Threads
Concurrent vs. Parallel vs. Distributed

• Concurrent
  
  \textit{# of control flows unrelated to \# of physical processors}

• Parallel
  
  \textit{# of control flows} \leq \textit{\# of physical processors; each flow has its own processor}

• Distributed
  
  \textit{Multiple machines connected via network}
Processes vs. Threads

• **Processes**
  – Possess own heap
  – Communicate via *IPC* (= inter-process communication) mechanisms
    • Sockets
    • Message passing
    • Etc.

• **Threads**
  – Contained within processes
  – Possess own stack, program counter
  – Share heap with other threads in same process
  – Communicate via shared memory

• **Historically**
  – Process management handled by operating system
  – Processes were single-threaded
(Single-Threaded) Processes

Process 1

- Thread
- Memory
- Heap
- Stack

Process 2

- Thread
- Memory
- Heap
- Stack

IPC
Multi-threaded Process
Running a Multi-Process / Multi-Threaded Application

• Execution requires processor
• Running a thread requires using a processor
• What decides which thread gets which processor?
  – Scheduler (part of operating system)!
  – Scheduling policy decides which threads run when
  – Pre-emptive schedulers can interrupt one thread and let another run on a given processor
    • Interrupted thread is “suspended”: its stack, program counter are saved so that thread can be re-activated later
    • Stack, program of new thread are loaded and new thread activated
    • This is called a context switch
Threads, Processes and Processors

• Do processes run on single machine? Yes
• Do processes run on a single processor? Not necessarily
  – Different threads can run on different processors
  – Scheduler makes this decision
• Do threads run on a single processor?
  – Usually
  – Some schedulers support *thread migration* (why?)
A Reference Model for Distributed / Parallel / Concurrent Programs
Language Support for Concurrency

• Many languages support concurrency!
  C, C++, C#, OCaml, Java, Scala, Erlang, Python, ...

• Traditionally: process / thread management handled via system calls to operating system
  – Not part of core language (e.g. C)
  – Platform-specific, non-portable, since different OS’s have different mechanisms

• Modern languages (e.g. Java, Scala, Erlang) include mechanisms for thread management directly
Java Concurrency

• Support for multi-threading, processes
  – Process = running instance of Java Virtual Machine
  – Objects live on heap, can be shared by threads in same process

• Every Java program has at least one thread: main

• This course: focus is on thread programming
Java Threads Are Objects

• Object class is `Thread`, which is part of `java.lang` package (automatically imported!)

• Thread objects include:
  – `public void run ()` executed when thread is launched
  – `public void start ()` to launch the thread
  – Other methods that we will study later
  – Constructors, of which more later, but here are two:
    • `Thread()` create a thread
    • `Thread(String name)` create a thread with the given name
Thread Creation in Java

• Create an object \texttt{t} in class \texttt{Thread} with desired functionality in \texttt{run()} method

• Invoke \texttt{t.start()}

• This starts a thread that runs the \texttt{t.run()} method!
“Desired Functionality in \texttt{run()}”? 

• Two approaches
  – \textbf{Subclassing from} \texttt{Thread}
  – \textbf{Implementing} \texttt{Runnable} \texttt{interface}

• In the former: \texttt{override} \texttt{run()} 

• In the second 
  – Define a class implementing the \texttt{Runnable} interface
  – Use relevant constructor in \texttt{Thread} on objects in this class

\begin{verbatim}
Thread (Runnable target)
Thread (Runnable target, String name)
\end{verbatim}
public class HelloWorldThread extends Thread {
    public void run () {
        System.out.println ("Thread says Hello World!");
    }
}

New class **HelloWorldThread** is introduced

- Extends Thread class
- Uses overriding to redefine `run()` method to do what we want
Thread Implementation via Runnable

public class HelloWorldRunnable implements Runnable {
    public void run () {
        System.out.println("Runnable says Hello World!");
    }
}

• Runnable is an interface in java.lang containing only:
  public void run ()

• This class implements Runnable by providing each object with a run() method

• Constructor for Thread class can now be called with objects in this class
Thread Creation

Thread h1 = new HelloWorldThread ();
Thread h2 = new Thread (new HelloWorldRunnable ());
h1.start ();
h2.start ();

• **h1** is thread object created from subclass of Thread
• **h2** is thread object created from Runnable object
• Output is two instances of “Hello World!”
# Subclassing or Runnable?

<table>
<thead>
<tr>
<th>PROS</th>
<th>Subclassing</th>
<th>Runnable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Easy access to Thread methods when implementing <code>run()</code></td>
<td>Can inherit from another class besides Thread when creating Runnable object</td>
<td></td>
</tr>
<tr>
<td>No need for creating intermediate object</td>
<td>Protects other Thread methods (e.g. start())</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CONS</th>
<th>Subclassing</th>
<th>Runnable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cannot inherit from another class</td>
<td>Harder to access non-static Thread methods when defining Runnable objects</td>
<td></td>
</tr>
<tr>
<td>Danger of overriding other methods in Thread class (e.g. start())</td>
<td>Must create intermediate Runnable object in order to create Thread</td>
<td></td>
</tr>
</tbody>
</table>
Thread States

• What happens if we do the following?

```java
Thread h1 = new HelloWorldThread ();
h1.start ();
h1.start ();
```

• Answer

```
Exception in thread "main"
java.lang.IllegalThreadStateException
```

• What?
  – Not every method is legal on every Thread object
  – The state of the object determines this validity
  – In this case, you cannot start a thread that has already been started
Thread States?

- Accessible via method `Thread.State getState()`
- `Thread.State` is an enumerated type recording state of thread object
  - **NEW**
    A thread that has not yet started is in this state.
  - **RUNNABLE**
    A thread executing in the Java virtual machine is in this state.
  - **BLOCKED**
    A thread that is blocked waiting for a monitor lock is in this state.
  - **WAITING**
    A thread that is waiting indefinitely for another thread to perform a particular action is in this state.
  - **TIMED_WAITING**
    A thread that is waiting for another thread to perform an action for up to a specified waiting time is in this state.
  - **TERMINATED**
    A thread that has exited is in this state.

[Quoted from http://docs.oracle.com/javase/6/docs/api/java/lang/Thread.State.html]
Thread State Example Revisited

Thread h1 = new HelloWorldThread (); // state is NEW
h1.start (); // state is RUNNABLE
h1.start (); // Error!

• When h1 is created, its state is NEW
• After h1.start () is called, the state is RUNNABLE
• h1.start () can only be called when state is NEW!
More on Thread States

• Some `Thread` methods (e.g. `start`) only applicable when object is in correct state
• The states `NEW`, `RUNNABLE`, `TERMINATED` are probably easiest to understand
• We will learn about the states `BLOCKED`, `WAITING`, `TIMED_WAITING` later
Other Thread State Methods

• **boolean isAlive()**
  – Returns true if thread has been started but is not terminated
  – t.isAlive() equivalent to
    \[(t.getState() != NEW) && (t.getState() != TERMINATED)\]
• **void join()**
  – Blocks until thread terminates, then terminates
  – t.join() very similar to
    \[while (t.isAlive()) \{ \} \]
• **void join (int millis)**
  Like t.join() except that if t has not terminated in millis
  milliseconds, then t.join(millis) nevertheless terminates
Threads and Process Termination

• A process (JVM) terminates when “there is nothing left that has to be done”

• When does this hold?
  – When the main thread terminates?
  – When all threads terminate?
  – When “the important” threads terminate?

• Java answer: when all user threads terminate
User Threads vs. Daemon Threads

• In Java, every thread object is by default a **user thread**
• A Java process can terminate if and only if all user threads (including, but not only, main) have terminated
• Threads may be changed to **daemon threads** using method `setDaemon(boolean on)`
  – If the only nonterminated threads are daemons, then the JVM will terminate
  – Daemon threads should only be used for “background work” needed while “useful” computation is being performed (e.g. updating status bars, etc.)
• `setDaemon()` is only valid if thread state is **NEW**; otherwise, `IllegalThreadStateException` thrown
More on Thread Termination

• When a thread object terminates, the object still remains!
  – Thread state is TERMINATED ...
  – ... but object still exists
Thread Execution

• Once threads are started, what determines when they are eligible for execution?
• Answer: scheduler!
  – Operating system routine responsible for allocating processor time to threads
  – If there are more processors than threads, could allocate each thread to its own processor
  – If there are more threads than processors, time-slicing may be needed to \textit{interleave} access to processors
  • Each thread executes for a while, then is pre-empted
  • Exact scheme also takes account of priorities, also whether or not threads are blocked
  • What if thread is in the middle of something “atomic”?
Scheduling Example (1)

One process and all its threads on a single CPU
Threads of a process allowed to run on either CPU
Methods for Interacting with Scheduler

- **void setPriority (int newPriority)**
  Set priority to given value (must be between MIN_PRIORITY and MAX_PRIORITY: see below)
- **int getPriority ()**
  Return priority value
- **static void yield ()**
  “Hint” to scheduler that thread can give up processor
- **static void sleep (int millis)**
  Block for millis milliseconds
- **static int MIN_PRIORITY**
  Smallest (lowest) priority
- **static int MAX_PRIORITY**
  Largest (highest) priority
- **static int NORM_PRIORITY**
  Default priority
InterruptedException

• **Thrown by some** Thread methods (**e.g.** sleep())
  – Raised when a thread is interrupted while sleeping
  – We will see about interruptions later

• **When you call such a method, you must either**
  – **Catch the exception, e.g.**
    ```java
    try { ... sleep (1000); ... }
    catch (InterruptedException e) { ... }
    ```
  – **... or include a throws directive in your method declaration, e.g.**
    ```java
    public void myMethod (...) throws InterruptedException { ... }
    ```
currentThread ()

static Thread currentThread ()

– Returns thread of current execution
– Useful when implementing thread operations via Runnable, as you can get access to thread info at runtime
