CMSC 330: Organization of Programming Languages

OCaml Data Types
OCaml Data

- So far, we’ve seen the following kinds of data
  - Basic types (int, float, char, string)
  - Lists
    - One kind of data structure
    - A list is either [ ] or h::t, deconstructed with pattern matching
  - Tuples and Records
    - Let you collect data together in fixed-size pieces
  - Functions

- How can we build other data structures?
  - Building everything from lists and tuples is awkward
User Defined Types

`type` can be used to create new names for types

- Like `typedef` in C – a name might be more useful for communicating intent than just the type structure

Example

```ocaml
# type mylist = int*(int list);;
type mylist = int * int list
# let empty : mylist = (0,[]);;
val empty : mylist = (0, [])
# let add x ((n,xs):mylist) : mylist = (n+1,x::xs);;
val add : int -> mylist -> mylist = <fun>
# let length ((n,_):mylist) = n;;
val length : mylist -> int = <fun>
# let x = add 1 (add 2 empty);;
val x : mylist = (2, [1; 2])
```

Annotation required to tell type inference you want `mylist`, not `int*int list`
(User-Defined) Variants

type coin = Heads | Tails

let flip x =
    match x with
    | Heads -> Tails
    | Tails -> Heads

let rec count_heads x =
    match x with
    | [] -> 0
    | (Heads::x') -> 1 + count_heads x'
    | (_,::x') -> count_heads x'

In simplest form:
Like a C `enum`

Basic pattern
matching
resembles C
`switch`

Combined list
and variant
patterns possible
Constructing and Destructing Variants

• Syntax
  • type \( t = C_1 \mid \ldots \mid C_n \)
  • the \( C_i \) are called constructors
    ➢ Must begin with a capital letter

• Evaluation
  • A constructor \( C_i \) is already a value
  • Destructing a value \( v \) of type \( t \) is done by pattern matching on \( v \); the patterns are the constructors \( C_i \)

• Type Checking
  • \( C_i : t \) (for each \( C_i \) in \( t \)'s definition)
Data Types: Variants with Data

- We can define variants that “carry data” too
  - Not just a constructor, but a constructor *plus values*

```haskell
type shape =
  Rect of float * float (* width*length *)
| Circle of float (* radius *)
```

- **Rect** and **Circle** are constructors
  - where a *shape* is either a `Rect(w, l)`
    - for any floats `w` and `l`
  - or a `Circle r`
    - for any float `r`
Data Types (cont.)

```ocaml
let area s =
  match s with
  | Rect (w, l) -> w *. l
  | Circle r -> r *. r *. 3.14

area (Rect (3.0, 4.0));; (* 12.0 *)
area (Circle 3.0);; (* 28.26 *)
```

- Use pattern matching to **deconstruct** values
  - Can bind pattern values to data parts
- Data types are **aka** algebraic data types and tagged unions
Data Types (cont.)

```haskell
type shape =
    Rect of float * float (* width*length *)
    | Circle of float       (* radius *)

let lst = [Rect (3.0, 4.0) ; Circle 3.0]
```

- What's the type of lst?
  - shape list

- What's the type of lst's first element?
  - shape
public interface Shape {
    public double area();
}

class Rect implements Shape {
    private double width, length;
    Rect (double w, double l) {
        this.width = w;
        this.length = l;
    }
    double area() {
        return width * length;
    }
}

class Circle implements Shape {
    private double rad;
    Circle (double r) {
        this.rad = r;
    }
    double area() {
        return rad * rad * 3.14159;
    }
}
Option Type

```plaintext
type optional_int =
    None
  | Some of int

let divide x y =
    if y != 0 then Some (x/y)
    else None

let string_of_opt o =
    match o with
        Some i -> string_of_int i
    | None -> "nothing"

let p = divide 1 0;;
print_string
    (string_of_opt p);;
(* prints "nothing" *)

let q = divide 1 1;;
print_string
    (string_of_opt q);;
(* prints "1" *)
```

- Comparing to Java: `None` is like `null`, while `Some i` is like an `Integer(i)` object
Polymorphic Option Type

- A Polymorphic version of option type can work with any kind of data
  - As int option, char option, etc...

```ocaml
type 'a option =
  Some of 'a
| None

let p = opthd [];; (* p = None *)
let q = opthd [1;2];; (* q = Some 1 *)
let r = opthd ["a"];; (* r = Some "a" *)
```

In fact, this option type is built into OCaml.

Polymorphic parameter: like Option<T> in Java.
type foo = (int * (string list)) list

Which one of the following could match foo?

A. [(3, “foo”, “bar”)]
B. [(7, [“foo”; “bar”])]
C. [(5, [“foo”, “bar”])]
D. [(9, [(“foo”, “bar”)])]
Quiz 1

type foo = (int * (string list)) list

Which one of the following could match foo?

A. [(3, “foo”, “bar”)]
B. [(7, [“foo”; “bar”])]  
C. [(5, [“foo”, “bar”])]  
D. [(9, [(“foo”, “bar”)])]}
Quiz 2: What does this evaluate to?

```ocaml
type num = Int of int | Float of float;;
let plus a b =
  match a, b with
  | Int i, Int j -> Int (i+j)
  | Float i, Float j -> Float (i +. j)
  | Float i, Int j -> Float (i +. float_of_int j)
  | ->

plus (Float 2.0) (Int 2);;
```

A. 4.0
B. Int 4
C. Float 4.0
D. Type Error
Quiz 2: What does this evaluate to?

```ocaml
type num = Int of int | Float of float;;
let plus a b =
  match a, b with
  | Int i, Int j -> Int (i+j)
  | Float i, Float j -> Float (i +. j)
  | Float i, Int j -> Float (i +. float_of_int j)
   ;;
plus (Float 2.0) (Int 2);;
```

A. 4.0
B. Int 4
C. Float 4.0
D. Type Error
Quiz 3: What does this evaluate to?

```
let foo f = match f with
    None -> 42.0
  | Some n -> n +. 42.0
;;
foo 3.3;;
```

A. 45.3
B. 42.0
C. Some 45.3
D. Error
Quiz 3: What does this evaluate to?

```
let foo f = match f with
  | None    -> 42.0
  | Some n  -> n +. 42.0
;;
foo 3.3;; foo (Some 3.3)
```

A. 45.3
B. 42.0
C. Some 45.3
D. Error
Recursive Data Types

- We can build up lists with recursive variant types

```ocaml
type 'a mylist =
  Nil
 | Cons of 'a * 'a mylist

let rec len = function
  Nil -> 0
 | Cons (_, t) -> 1 + (len t)

len (Cons (10, Cons (20, Cons (30, Nil))))
(* evaluates to 3 *)
```

- Won’t have nice [1; 2; 3] syntax for this kind of list
Variants (full definition)

- Syntax
  - \texttt{type } \texttt{t} = \texttt{C1 [of t1]} \mid \ldots \mid \texttt{Cn [of tn]}
  - the \textit{Ci} are called \textbf{constructors}
    - Must begin with a capital letter; may include associated data
    - notated with brackets \([\) to indicate it’s optional

- Evaluation
  - A constructor \textit{Ci} is a value if it has no assoc. data
    - \textit{Ci vi} is a value if it does
  - Destructuring a value of type \textit{t} is by pattern matching
    - patterns are constructors \textit{Ci} with data components, if any

- Type Checking
  - \textit{Ci [vi]} : \textit{t [if vi has type ti]}
exception My_exception of int
let f n =
  if n > 0 then
    raise (My_exception n)
  else
    raise (Failure "foo")
let bar n =
  try
    f n
  with My_exception n ->
    Printf.printf "Caught %d\n" n
| Failure s ->
    Printf.printf "Caught %s\n" s
Exceptions (cont.)

- Exceptions are declared with `exception`
  - They may appear in the signature as well
- Exceptions may take arguments
  - Just like type constructors
  - May also have no arguments
- Catch exceptions with `try...with...`
  - Pattern-matching can be used in `with`
  - If an exception is uncaught
    - Current function exits immediately
    - Control transfers up the call chain
    - Until the exception is caught, or until it reaches the top level
OCaml Exceptions (cont.)

- **failwith**: Raise exception `Failure` with the given string.
- **invalid_arg**: Raise exception `Invalid_argument` with the given string
- **Not_found**: Raised if the object does not exist

```ocaml
let div x y =  
  if y = 0 failwith "divide by zero" else x/y;;
let lst =[(1,"alice");(2,"bob");(3,"cat")];;
let lookup key lst =
  try  
    List.assoc key lst
  with
  Not_found -> "key does not exist"
```
