

# CMSC 132: Object-Oriented Programming II

---

## Threads in Java

**Department of Computer Science**  
**University of Maryland, College Park**

# Problem

- **Multiple tasks for computer**
  - Draw & display images on screen
  - Check keyboard & mouse input
  - Send & receive data on network
  - Read & write files to disk
  - Perform useful computation (editor, browser, game)
- **How does computer do everything at once?**
  - Multitasking
  - Multiprocessing

# Multitasking (Time-Sharing)

## ■ Approach

- Computer does some work on a task
  - Computer then quickly switch to next task
  - Tasks managed by operating system (scheduler)
- Computer **seems** to work on tasks concurrently
- Can improve performance by reducing waiting

# Multitasking Can Aid Performance

## ■ Single task

## ■ Two tasks

# Multiprocessing (Multithreading)

## ■ Approach

- Multiple processing units (**multiprocessor**)
- Computer works on several tasks in parallel
- Performance can be improved

Dual-core  
AMD  
Athlon X2

32  
processor  
Pentium  
Xeon

4096  
processor  
Cray X1

Beowulf computer  
cluster (Borg, 52-  
node cluster used  
by McGill University  
Image/Info from  
Wikipedia )

# Perform Multiple Tasks Using...

## 1. Process

- Definition – executable program loaded in memory
- Has own **address space**
  - Variables & data structures (in memory)
- Each process may execute a different program
- Communicate via operating system, files, network
- May contain multiple threads

# Perform Multiple Tasks Using...

## 2. Thread

- Definition – sequentially executed stream of instructions
- Shares address space with other threads
- Has own **execution context**
  - Program counter, call stack (local variables)
- Communicate via shared access to data
- Multiple threads in process execute **same** program
- Also known as “lightweight process”
- Let’s see how memory is organized for a threaded environment

# Motivation for Multithreading

## 1. Captures logical structure of problem

- May have concurrent interacting components
- Can handle each component using separate thread
- Simplifies programming for problem

## ■ Example

Web Server uses  
threads to handle ...

Multiple simultaneous  
web browser requests

# Motivation for Multithreading

## 2. Better utilize hardware resources

- When a thread is delayed, compute other threads
- Given extra hardware, compute threads in parallel
- **Reduce overall execution time**

### ■ Example

# Multithreading Overview

## ■ Motivation & background

## ■ Threads

### ■ Creating Java threads

### ■ Thread states

### ■ Scheduling

## ■ Synchronization

### ■ Data races

### ■ Locks

### ■ Deadlock

# Programming with Threads

## ■ Concurrent programming

- Writing programs divided into independent tasks
- Tasks may be executed in parallel on multiprocessors

## ■ Multithreading

- Executing program with multiple threads in parallel
- Special form of multiprocessing

# Creating Threads in Java

- Need to specify work performed by thread

- Two approaches

1. Runnable interface (Preferred Approach)

```
public interface Runnable {  
    public void run(); // work ⇒ thread  
}
```

2. Extending Thread class

```
public class Thread extends Object { ... }
```

# Thread Class

```
public class Thread extends Object
    implements Runnable {
    public Thread();
    public Thread(String name); // Thread name
    public Thread(Runnable R); // Thread ⇒ R.run()
    public Thread(Runnable R, String name);

    public void run(); // if no R, work for thread
    public void start(); // begin thread execution
    ...
}
```

# Creating Threads in Java

## ■ Runnable Approach

1. Define class implementing Runnable interface

```
public interface Runnable {  
    public void run( );  
}
```

2. Put work to be performed in run( ) method

3. Create instance of the “worker” class

4. Create thread to run it

### ■ Create Thread object

- Pass worker object to Thread constructor
- Or hand the worker instance to an executor
- Alternative methods for running threads

# Creating Threads in Java

## ■ Example

```
public class MyT implements Runnable {  
    public void run( ) {  
        ... // work for thread  
    }  
}
```

```
Thread t = new Thread(new MyT( )); // create thread  
t.start();                        // begin running thread  
...                               // thread executing in parallel
```

## ■ See Message example in code distribution

# Alternative Thread Creation Approach

## ■ Thread Class Approach

- Extend Thread class and override run method
- Not recommended

## ■ Example

```
public class MyT extends Thread {  
    public void run( ) {  
        ...                // work for thread  
    }  
}  
MyT t = new MyT( ) ;    // create thread  
t.start( );             // begin running thread  
...                     // thread executing in parallel
```

## ■ See Message example in code distribution

# Why Not Recommended?

- **Not a big problem for getting started**
  - **But a bad habit for industrial strength development**
- **Methods of worker and Thread class intermixed**
- **Hard to migrate to more efficient approaches**
  - **Thread Pools**

# More Thread Class Methods

```
public class Thread extends Object {  
    ...  
    public static Thread currentThread()  
    public String getName()  
    public void interrupt()  
    public boolean isAlive()  
    public void join()  
    public void setDaemon()  
    public void setName()  
    public void setPriority()  
    public static void sleep()  
    public static void yield()  
}
```

# Creating Threads in Java

## ■ Note

- Thread eventually starts executing **only if start() is called**

- Runnable is interface
  - So it can be implemented by any class
  - Required for multithreading in applets
- Do not call the run method directly

# Threads – Thread States

- **Java thread can be in one of these states**
  - **New** – thread allocated & waiting for start()
  - **Runnable** – thread can begin execution
  - **Running** – thread currently executing
  - **Blocked** – thread waiting for event (I/O, etc.)
  - **Dead** – thread finished
- **Transitions between states caused by**
  - **Invoking methods in class Thread**
    - **new(), start(), yield(), sleep(), wait(), notify()...**
  - **Other (external) events**
    - **Scheduler, I/O, returning from run()...**
- **In Java states defined by Thread.State**

# Threads – Thread States

## ■ State diagram

**Running** is a logical state → indicates runnable thread is actually running

# Daemon Threads

## ■ Java threads types

- User

- Daemon

- Provide general services
- Typically never terminate
- Call `setDaemon()` before `start()`

## ■ Program termination

1. All user threads finish
2. Daemon threads are terminated by JVM

# Threads – Scheduling

## ■ Scheduler

- Determines which runnable threads to run
- Can be based on thread **priority**
- Part of OS or Java Virtual Machine (JVM)

## ■ Scheduling policy

- Nonpreemptive (cooperative) scheduling
- Preemptive scheduling

# Threads – Non-preemptive Scheduling

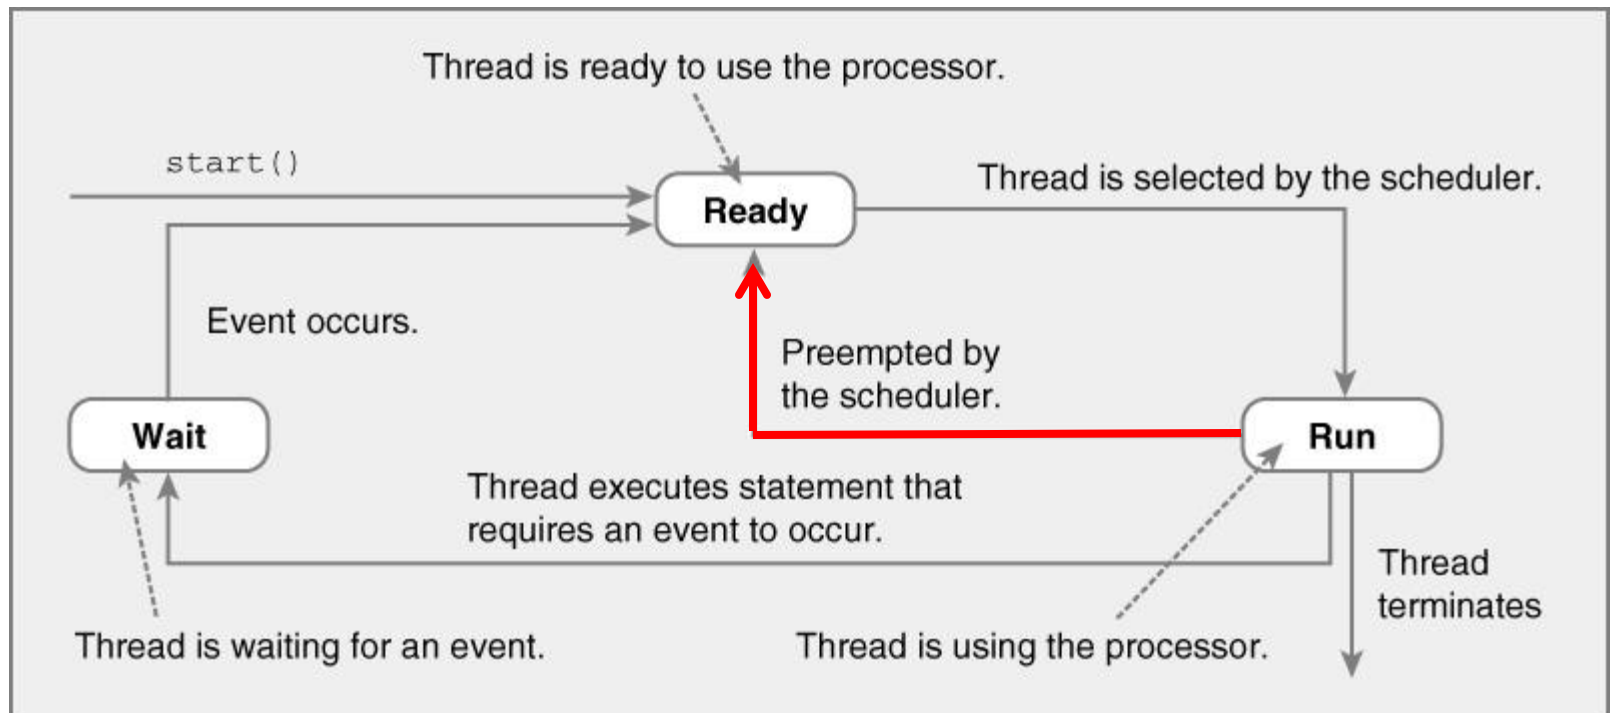

- Threads continue execution until
  - Thread terminates
  - Executes instruction causing wait (e.g., IO)
  - Thread volunteering to stop (invoking yield or sleep)

# Threads – Preemptive Scheduling

- Threads continue execution until
  - Same reasons as non-preemptive scheduling
  - **Preempted** by scheduler

# Java Thread Example

```
public class ThreadNoJoin extends Thread {  
    public void run() {  
        for (int i = 0; i < 3; i++) {  
            try {  
                sleep((int)(Math.random() * 5000)); // 5 secs  
            } catch (InterruptedException e) { e.printStackTrace(); }  
            System.out.println(i);  
        }  
    }  
    public static void main(String[] args) {  
        Thread t1 = new ThreadNoJoin();  
        Thread t2 = new ThreadNoJoin();  
        t1.start();  
        t2.start();  
        System.out.println("Done");  
    }  
}
```

# Java Thread Example – Output

## ■ Possible outputs

- 0,1,2,0,1,2,Done // thread 1, thread 2, main()
- 0,1,2,Done,0,1,2 // thread 1, main(), thread 2
- Done,0,1,2,0,1,2 // main(), thread 1, thread 2
- 0,0,1,1,2,Done,2 // main() & threads interleaved

main (): thread 1, thread 2, println Done

thread 1: println 0, println 1, println 2

thread 2: println 0, println 1, println 2

# Thread Class – join() Method

- Can wait for thread to terminate with join( )
- Method prototype
  - `public final void join( )`
    - Returns when thread is done
    - Throws InterruptedException if interrupted

# Java Thread Example (Join)

```
public class ThreadJoin extends Thread {  
    public void run() {  
        for (int i = 0; i < 3; i++) {  
            try {  
                sleep((int)(Math.random() * 5000)); // 5 secs  
            } catch (InterruptedException e) { e.printStackTrace(); }  
            System.out.println(i);  
        }  
    }  
}  
  
public static void main(String[] args) {  
    Thread t1 = new ThreadJoin();  
    Thread t2 = new ThreadJoin();  
    t1.start();  
    t2.start();  
    try {  
        t1.join();  
        t2.join();  
    } catch (InterruptedException e) { e.printStackTrace(); }  
    System.out.println("Done");  
}  
}
```

# About Join

- **Important:** You will limit the concurrency level if you do not start/join correctly
- Suppose you want to run many threads concurrently. **Start them all and then execute the join for each one.** Do not start one thread, then join on that thread, start the second one, join on that thread, etc.
- Feel free to use arrays, sets, etc. to keep track of your threads

# Thread Scheduling Observations

- Order thread is selected is **indeterminate**
  - Depends on scheduler
- Scheduling may not be fair
  - Some threads may execute more often
- Thread can block indefinitely (starvation)
  - If other threads always execute first

# About Threads

- **Common mistake** → calling the `run()` method. If you want to run a thread you must execute `start()` and not call the `run()` method; the `run()` method is called for you.
- **Thread.sleep** → Suppose you have a thread object reference (`t1`) and invoke `t1.sleep(2000)`. Which thread will be sleeping for 2 seconds? It will not be `t1`.

# Thread Example

- **Swing uses a single-threaded model**
- **Long computations in the EDT freezes the GUI**
- **Example: Progress Bar Example**
