Object-Oriented Programming I

Introduction to Arrays

Dept of Computer Science
University of Maryland College Park

This material is based on material provided by Ben Bederson, Bonnie Dorr, Fawzi Emad, David Mount, Jan Plane
Overview

- Arrays
Arrays

- **Data structure** ➔ mechanism for storing data in a structured way
- **Problem** ➔ You need to keep track of the scores of students in a class
  - Declaring and handling 50 variables is not an easy task
  - Arrays come to the rescue
- **Array** ➔ Collection of values that can be treated as a unit or individually.
  
  \[ a = \text{new} \text{ int}[5]; \]
- You can visualize an array as a set of variables one after another
Arrays

- **Array** ➔ a very useful data structure provided by Java and other programming languages
- **Array** ➔ sequence of variables of the same type
  - Homogeneous data structure
  - Size (quantity) fixed when space is allocated
  - Ordered
- Individual elements of sequence can be referenced, updated, etc.
- Arrays are objects (hence allocated on heap) with a reference on the stack
- Like other objects, “instance variables” of array = cells in array are assigned default values (0 / null / etc.) when array is created
- Let’s draw a memory map representing an array
- Variable that represents the array can be seen as storing the address of the first element of the array
Array Indexing

- Java provides a special syntax for uniformly accessing cells in an array
  - Declaration of a:
    ```java
    int[] a;
    ```
  - Allocation of space for array named a:
    ```java
    a = new int[5]; // or combined: int[] a = new int[5];
    ```
    - This creates five int variables “named”: a[0], a[1], a[2], a[3], a[4]
  - To modify contents of cell #2 to 6 and cell #1 to 74:
    ```java
    a[2] = 6;
    a[1] = 74;
    ```
  - To use the contents of cell #2 and cell #1:
    ```java
    System.out.println("value = " + (a[1] - a[2]));
    ```
- This access mechanism to the individual elements is called **array indexing**
  - In Java / C / C++, array cells are indexed beginning at 0 and going up to n-1 (where n is number of cells)
  - Beware: start at 0! and end at one less than the size!!
  - If we assume the array name represents the address of the first array entry, then the index value represents how many units to move forward
- **Example:** ReadValues.java
Square Brackets: [ ] and length

- Three uses in Java:
  - Array variable declaration → int[] a
  - Array object creation → new int[10]
  - Array indexing → a[0]
- Arrays also have a.length value that holds the amount of space currently allocated for that array
To maintain consistency with C / C++, following declaration of array variables also possible:

```c
int grade[];
```

Compare to Java standard:

```java
int[] grade;
```

Java standard generally preferred

- “type[]” emphasizes array status

Alternative syntax sometimes handy:

```c
int grade[], size, gpa[];
```

- Declares two arrays of base type int: grade, gpa
- Declares a single int variable: size
Arrays are:
- Sequences of cells holding values of the same type (“base type”)
- Objects (hence created using new)

To define an array variable:
```java
int[] a;  // an array with base type int
```

To create an array object:
```java
a = new int[10];
```
- Creates an array of 10 cells on the heap
- The base type is int

To access individual array cells → use indexing
- `a[0], a[1], ..., a[9]`
- Cells are just like variables:
  - They may be read → `x = a[3];`
  - They may be written → `a[2] = 7;`

**Example:** GeneratingRandomValues.java
To process all elements in array ...

Do the following:

```java
for (int i = 0; i < a.length; i++){
    ...process the one element at a[i]...
}
```

- Use fresh loop counter to avoid overwriting another variable of same name elsewhere
- Remember:
  - Use 0 as one end of the array, not 1
  - Use $i < a.length$ as the other end, not $i \leq a.length$
Does the following copy a into b?
```
int[] a = new int[5];
int[] b = a;
No!: a, b are aliases!
```

How to make a copy?
```
int[] a = new int[5];
int[] b = new int[a.length];
for (int i = 0; i < a.length; i++){
    b[i] = a[i];
}
```
Making Arrays Bigger

- Suppose we want to make an array bigger by adding an element.
- Does the following work?
  ```java
  int[] a = new int[5];
  a.length++;  
  ```
- **No!**
  - We get the following:
    ```java
    Exception in thread "main" java.lang.Error: Unresolved compilation problem:
    The final field array.length cannot be assigned
    at Sample.main(Sample.java:15)
    ```
  - a.length is immutable
  - No assignment to it is allowed.
To Make an Array Bigger...

- Create a new larger array object
- Copy old array contents into new object
- Assign address of new object to variable

```java
int[] a = new int[5];
int[] temp = new int[a.length + 1];
for (int i = 0; i < a.length; i++){
    temp[i] = a[i];
}
a = temp;
```

- New variable `temp` created to hold copy
- Previous contents of `a` become garbage

- Usually when you grow an array you allocate an array that is twice the size of the original array. This approach is more efficient than growing the array one element at a time
- How we know? Amortized analysis.
