

CMSC412

Project 0

Administrivia

- <http://www.cs.umd.edu/class/fall2009/cmssc412/>
- CSIC 2118, MW 9:00-9:50 / 10:00-10:50
- John Silberholz (josilber@umd.edu)
- Calvin Grunewald (cgrunewa@gmail.com)
- TAs
 - Bo Han (bohan@cs.umd.edu)
 - Vasilieos Lekakis (lex@cs.umd.edu)

Why are we here?

- To get you started on the project and answer your questions
- Give you background material
- Show you how the concepts you learn in lecture apply to GeekOS
- Come with questions

Why are operating systems such a big deal?

Semester Project

- Parallel to lecture
- Lots of code
 - Heavily commented
 - Read it!
- Use the forum
 - Quickest way to get questions answered
- Come to recitation with questions
- These projects are challenging, but fun

Best advice for success

- Start early
 - Seriously
 - No, for real

Getting Started

- Getting the source
 - svn co
<https://svn.cs.umd.edu/repos/geekos/project0>
 - Uname: “sv-geekosro”; passwd: “”
- Setup instructions are on the website:
 - QEMU, Compilers, Debuggers
 - Linux, Mac, and Linuxlab
 - Cygwin
 - GeekOS build

GeekOS Emulation Environment

- GeekOS
- QEMU (Hardware emulator)
- Linux/Mac
- Real Hardware

Project 0

- Project requirements
 - Resource restrictions on GeekOS processes:
 - # of active processes
 - # of syscalls by a single process

System calls

- Software interrupt
 - The only interrupt callable from user level:
idt.c Init_IDT
 - SYSCALL_INT: 0x90
- Operation: syscall.h; syscall.c; libc/process.c
 - Put args in registers on user side; raise INT
 - Recover them on kernel side
 - Call the appropriate Sys_xxxx
 - Return result/error code in appropriate register
- Use *g_CurrentThread* for information about who raised it

Threads

- Each thread is a Kernel_Thread object:
kthread.h
- Current thread: g_CurrentThread (global)
- User mode threads
 - Kernel_Thread with a populated User_Context
- Transfer from user to kernel mode: *syscall*
- Kernel vs. user memory
 - One from user view and one from kernel
 - Kernel needs to access user memory (but not vice versa!)
 - Use Copy_From_User/Copy_To_User

The system queues

- Thread_Queue structure
- Run Queue:
 - Threads which are ready to run, but not currently running
 - GeekOS has one run queue (for now.....)
- Wait Queues:
 - Threads that are waiting for a specific event or on a specific device (keyboard/network/other threads)
 - *geekos/kthread.c* Join()
 - Follow Get_Key syscall to see how the thread gets in the keyboard wait queue

Interrupts

- Types:
 - Illegal operations (result in kills)
 - Faults (like page faults; not of concern now)
 - Hardware interrupts
 - Software interrupts (traps): syscall int
- Interrupt handlers
 - *geekos/int.c*
 - On completion control returns to the thread that was interrupted

Interrupts

- When you don't want them:
 - When modifying global structures, queues, etc.
 - When you want an atomic operation
 - Disable_Interrupts() / Enable_Interrupts()
 - *include/geekos/int.h*
 - Use caution (interrupt state dependent)
 - Enable_Interrupts() when finished
 - See examples: *src/geekos/user.c*:
Attach_User_Context()
 - Begin_Int_Atomic() / End_Int_Atomic
 - Oblivious way of saving and restoring interrupt state
