

Parsing Wrapup

Roadmap (Where are we?)

Last lecture

- Shift-reduce parser
- LR(1) parsing
 - LR(1) items
 - Computing closure
 - Computing goto
 - LR(1) canonical collection

This lecture

- LR(1) parsing
 - Building ACTION / GOTO tables
 - Shift/reduce and reduce/reduce conflicts
 - SLR(1), LALR(1), operator precedence
 - Error recovery

CS430

2

Filling in the LR(1) ACTION and GOTO Tables

The algorithm

$\forall$ set $s_x \in S$
 $\forall$ item $i \in s_x$
 if i is $[A \rightarrow \beta \cdot a, \gamma, b]$ and $\text{goto}(s_x, a) = s_k, a \in T$ // $\cdot$ to left of terminal a
 then $\text{ACTION}[x, a] \leftarrow \text{"shift } k"$ // $\rightarrow$ shift if lookahead = a
 else if i is $[S' \rightarrow S \cdot, \$]$ // start production done,
 then $\text{ACTION}[x, \$] \leftarrow \text{"accept"}$ // $\rightarrow$ accept if lookahead = $\$$
 else if i is $[A \rightarrow \beta \cdot, \gamma]$ // all the way to right
 then $\text{ACTION}[x, \gamma] \leftarrow \text{"reduce } A \rightarrow \beta"$ // $\rightarrow$ production done
 $\forall n \in NT$ // reduce if lookahead = a
 if $\text{goto}(s_x, n) = s_k$
 then $\text{GOTO}[x, n] \leftarrow k$ // store transitions for nonterminals

Many items
generate no
table entry

e.g., $[A \rightarrow \beta Bx, \gamma]$ does not,
but closure ensures that all
the rhs' for B are in s_x

Example - Building LR(1) ACTION and GOTO Table

What can go wrong?

What if set s contains $[A \rightarrow \beta \cdot \gamma, b]$ and $[B \rightarrow \beta \cdot \gamma, a]$?

- First item generates "shift", second generates "reduce"
- Both define $ACTION[s, a]$ — cannot do both actions
- This is a fundamental ambiguity, called a **shift/reduce conflict**

What if set s contains $[A \rightarrow \gamma \cdot, a]$ and $[B \rightarrow \gamma \cdot, a]$?

- Each generates "reduce", but with a different production
- Both define $ACTION[s, a]$ — cannot do both reductions
- This fundamental ambiguity is called a **reduce/reduce conflict**

In either case, the grammar is not LR(1)

Solutions

- Modify grammar to eliminate conflict
- Specify how conflict should be resolved
→ Can be used to assign precedence & associativity (to operators)

Shift/reduce Error Example

- Grammar

P1	$S \rightarrow E$
P2	$E \rightarrow E + E$
P3	$E \rightarrow a$

- State in canonical collection of LR(1) items

$[E \rightarrow E + E \cdot, \{ \$, + \}]$
 $[E \rightarrow E \cdot + E, \{ \$, + \}]$

- Entry in ACTION / GOTO table for lookahead +

shift 3
reduce P2
($E \rightarrow E + E$)

CS430

9

Reduce/reduce Error Example

- Grammar

P1	$S \rightarrow E$
P2	$E \rightarrow A$
P3	$A \rightarrow a$
P4	$A \rightarrow a$

- State in canonical collection of LR(1) items

$[E \rightarrow a \cdot, \$]$
 $[A \rightarrow a \cdot, \$]$

- Entry in ACTION / GOTO table for lookahead \$

reduce P3 ($E \rightarrow a$)
reduce P4 ($A \rightarrow a$)

CS430

10

Left Recursion versus Right Recursion

- Right recursion

→ Required for termination in top-down parsers
 → Produces right-associative operators

- Left recursion

→ Works fine in bottom-up parsers
 → Limits required stack space
 → Produces left-associative operators

- Rule of thumb

→ Left recursion for bottom-up parsers
 → Right recursion for top-down parsers

CS430

11

Associativity

- Normally defined by programming language
- What difference does it make?
- Can change answers in floating-point arithmetic
- Exposes a different set of common subexpressions

- Consider $x+y+z$

- What if $y+z$ occurs elsewhere? Or $x+y$ or $x+z$?
- What if $x = 2$ & $z = 17$? Neither left nor right exposes 19
 → I.e., optimizer cannot replace $x+z$ with 19 in output code

CS430

12

Resolving Conflicts

- Precedence and associativity may be used to resolve conflicts in ambiguous grammars
- When comparing operator on stack with lookahead
 - Shift if lookahead has
 - Higher precedence
 - Same precedence, right associative
 - Reduce if lookahead has
 - Lower precedence
 - Same precedence, left associative
- Advantage
 - Can use smaller (ambiguous) grammars
 - Example
 - $E \rightarrow E + E \mid E - E \mid E * E \mid E / E \mid - E \mid id \mid num$

CS430

13

Operator Precedence Grammars

- Alternative approach to shift-reduce parsing
- Given a sentential form $aABb$, three possibilities
 - A in handle, B not in handle
→ A is reduced before B
 $A > B$
 - A and B both in handle
→ A and B reduced at same time
 $A = B$
 - B in handle, A not in handle
→ B is reduced before A
 $B > A$
- Handle is composed of
 - $< >, < = >, < = = >, < = = = >, \text{etc...}$
- To decide whether to shift or reduce, compare top of stack with lookahead (ignoring nonterminals)
 - Shift if $< \text{ or } =$
 - Reduce if $>$ (left end of handle is closest $<$ to top of stack)

CS430

14

Operator Precedence Grammar Example

The Grammar

$$E ::= E + E \mid E * E \mid id$$

	+	*	id	\$
+	<	<	<	<
*	>	<	<	<
id	<	<	<	<
\$	<	<	<	<

Stack	Input	Precedence
\$	id + id * id \$	\$ < id
\$ < id	+ id * id \$	id > +
\$ < E	+ id * id \$	\$ < +
\$ < E +	id * id \$	+ < id
\$ < E + < id	* id \$	id > *
\$ < E + < E	* id \$	+ < *
\$ < E + < E *	id \$	* < id
\$ < E + < E * < id	\$	id > \$
\$ < E + < E * E	\$	* > \$
\$ < E + E	\$	+ > \$
\$ < E	\$	\$ > \$

CS430

15

Shrinking the ACTION/GOTO Tables

Three options:

- Combine terminals such as number & identifier, $+$ & $-$, $*$ & $/$
 - Directly removes a column, may remove a row
 - For expression grammar, 198 (vs. 384) table entries
- Combine rows or columns (table compression)
 - Implement identical rows once & remap states
 - Requires extra indirection on each lookup
 - Use separate mapping for ACTION & for GOTO
- Use another construction algorithm
 - Both SLR(1) and LALR(1) produce smaller tables
 - Implementations are readily available

CS430

16

SLR(1) Parser

- Build ACTION / GOTO table using LR(0) items
 - Problem - when to perform reduction for $A \rightarrow \beta$?
 - Solution - reduce $A \rightarrow \beta$ only when lookahead $\in \text{FOLLOW}(A)$
- Algorithm

```

forall s_x in S
  forall item in s_x
    if i is [A -> beta . a gamma] and goto(s_x, a) = s_y, a in T
      then ACTION[x, a] <- "shift k" // -> shift if lookahead = a
    else if i is [S -> S .]
      then ACTION[x, $] <- "accept" // -> accept if lookahead = $
    else if i is [A -> beta .] and a in FOLLOW(A)
      then ACTION[x, a] <- "reduce A -> beta" // -> reduce if lookahead
      // is in FOLLOW(A)
  forall n in NT
    if goto(s_x, n) = s_k
      then GOTO[x, n] <- k // store transitions for nonterminals
  
```

CS430

17

Example - SLR(1) Parser

CS430

18

LALR(1) Parser

- Core of set of LR(1) items
 - Set of LR(0) items derived by ignoring lookahead symbols
 - Example

LR(1) state	LR(0) state
$[E \rightarrow a \cdot, b]$ $[A \rightarrow a \cdot, c]$	$[E \rightarrow a \cdot]$ $[A \rightarrow a \cdot]$
- LALR(1) parser
 - Merge two sets of LR(1) items (states), if same core
- Result
 - Potentially much smaller set of states
 - Same as SLR(1) parser
 - May introduce reduce/reduce conflicts
 - Will **not** introduce shift/reduce conflicts

CS430

19

Example - LALR(1) Parser

- Merging states

$[E \rightarrow a \cdot, b]$ $[A \rightarrow ba \cdot, c]$	can be merged with	$[E \rightarrow a \cdot, d]$ $[A \rightarrow ba \cdot, b]$
---	--------------------	---
- Resulting state

$[E \rightarrow a \cdot, b]$ $[A \rightarrow ba \cdot, b]$ $[E \rightarrow a \cdot, d]$ $[A \rightarrow ba \cdot, c]$
--
- Introduces reduce/reduce error
 - Can reduce either $E \rightarrow a$ or $A \rightarrow ba$ for lookahead = b

CS430

20

LR(k) versus LL(k) (Top-down Recursive Descent)

Finding Reductions

LR(k) ⇒ Each reduction in the parse is detectable with

- Complete left context (everything to left of handle)
- Reducible phrase (handle) itself
- k terminal to right of handle

LL(k) ⇒ Parser must select the next rule based on

- Complete left context (everything up to & including NT to expand)
- k terminals to right of nonterminal to expand

Thus, LR(k) is more powerful since it examines more context

For example, consider grammar $S \rightarrow ab \mid aa$

- LL(1)?
 - No, cannot decide which production with lookahead = a
- LR(1)?
 - Yes, can shift ab or aa onto stack before deciding on reduction

CS430

21

LR(k) Parsers

- Properties
 - Strictly more powerful than LL(k) parsers
 - Most general non-backtracking shift-reduce parser
 - Detects error as soon as possible in left-to-right scan of input
 - Contents of stack are **viable prefixes**
 - Possible for remaining input to lead to successful parse

CS430

22

LR(k) versus LL(k) Summary

	Advantages	Disadvantages
Top-down recursive descent	Fast Good locality Simplicity Good error detection	Hand-coded High maintenance Right associativity
LR(1)	Fast Deterministic langs. Automatable Left associativity	Large working sets Poor error messages Large table sizes

CS430

23

LR(0) versus SLR(1) versus LR(1)

Example grammar

$$S' \rightarrow S$$

$$S \rightarrow S ; a \mid a$$

LR(0) ?

LR(1) ?

SLR(1) ?

CS430

24

LALR(1) versus LR(1)

Example grammar

$$\begin{aligned} S' &\rightarrow S \\ S &\rightarrow aAd \mid bBd \mid aBe \mid bAe \\ A &\rightarrow c \\ B &\rightarrow c \end{aligned}$$

LR(0) ?

LR(1) ?

LALR(1) ?

CS430

27

Error Recovery in Shift-Reduce Parsers

The problem: parser encounters an invalid token

Goal: Want to parse the rest of the file

Basic idea (panic mode):

- Assume something went wrong while trying to find handle for nonterminal A
- Pretend handle for A has been found; pop "handle", skip over input to find terminal that can follow A

Restarting the parser (panic mode):

- find a restartable state on the stack (has transition for nonterminal A)
- move to a consistent place in the input (token that can follow A)
- perform (error) reduction (for nonterminal A)
- print an informative message

CS430

28

Error Recovery in YACC (ASU p.264)

Yacc's (bison's) error mechanism (note: version dependent!)

- designated token **error**
- used in error productions of the form
 $A \rightarrow \beta \text{ error } \alpha$
- α specifies synchronization points

When error is discovered

- pops stack until it finds state where it can shift the **error** token
- resumes parsing to match α
- special cases:
 - $\alpha = w$, where w is string of terminals: skip input until w has been read
 - $\alpha = \epsilon$: skip input until state transition on input token is defined
- error productions can have actions

CS430

29

Error Recovery in YACC

```

cmpdstmt: BEG stmt_list END
stmt_list : stmt
           | stmt_list ';' stmt
           | error { yyerror("\n***Error: illegal statement\n"); }
    
```

This should

- throw out the erroneous statement
- synchronize at ";" or "end" (implicit: $\alpha = \epsilon$)
- writes message "***Error: illegal statement" to `stderr`

Example: begin a & 5 | hello ; a := 3 end

↑ resume parsing
***Error: illegal statement
