

Advanced Compilation Topics

Some slides thanks to Prof. K. Hazelwood @ UVA

Just-In-Time (JIT) Compilation

- Approach
 - Compile portions of code (or entire program) at run time
 - Compilation time becomes execution time
- Combination of compiler & interpreter
 - Achieve speed of compiled code
 - Take advantage of benefits of interpreter
- Advantages
 - Can target specific architecture (e.g., Xeon vs x86)
 - Can perform optimizations on dynamically linked library code
 - Can run compiler in sandbox for safety
- Java extensively uses JIT
 - Transforms Java source into Java byte code
 - Byte code is more compact than source code
 - JIT compilation on byte code is simpler / faster than on Java source

Run-time Optimization

- Approach
 - Compiler identifies important conditions in code
 - Compiler then generates for each condition
 - Run time test for condition
 - Multiple versions of code optimized for different condition, or optimized code that can be parameterized at run time
 - Program dynamically selects version (or changes parameters) at run time
- Advantages
 - Resulting programs can adapt at run time to a variety of conditions
- Approach can be extended to “compiling” binary files
 - Applying run-time optimization to binaries directly w/o source

CS430

5

Advanced topics

- Static Compilation
 - All work is done ahead of time
- Just-in-Time Compilation
 - Compile parts of program at run time
- Profile-based optimization
 - Use run-time profile to guide optimization
- Run-time optimization
 - Include multiple options in binary
- Compiling for GPUs
 - Handle specialized libraries & algorithms
- Compiling for low power
 - Reducing power usage

CS430

2

Profile-based Compilation

- Approach
 - Compiler inserts instrumentation in program
 - Run instrumented program on representative input → profile
 - Recompile using profile to guide optimization → optimized code
- Advantages
 - Can obtain more information than static analysis
 - Identify frequently executed code
 - Identify likely result of conditional branches
 - Estimate loop iterations
 - No run time overhead for final optimized code
- Disadvantages
 - Longer compilation / optimization process
 - Actual application behavior may not match representative input

6

Compiling for GPUs

- Approach
 - GPUs can compute vector / stream operations in parallel
 - Using special libraries (e.g. CUDA) to copy / process data
 - Requires programs for both CPU & GPU
 - Compiler can simplify process of generating GPU code
 - PGI compiler relies on user-inserted annotations to specify parallel region, vector operations
- Advantages
 - Supercomputer-like FP performance on commodity processors
- Disadvantages
 - Performance tuning difficult
 - Large speed gap between compiler-generated and hand-tuned code

CS430

7

Compiling for GPUs - Matrix Multiplication Example

```
• Original Fortran
do i = 1,n
  do j = 1,m
    do k = 1,p
      a(i,j) = a(i,j) + b(i,k)*c(k,j)
    enddo
  enddo
enddo
```

CS430

8

Compiling for GPUs - Matrix Multiplication Example

- Annotated Fortran for PGI compiler (compiled to CUDA)

```
!$acc region
!$acc do parallel
do j=1,m
  do k=1,p
    !$acc do parallel, vector(2)
    do i=1,n
      a(i,j) = a(i,j) + b(i,k)*c(k,j)
    enddo
  enddo
enddo
!$acc end region
```

Compiling for GPUs - Matrix Multiplication Example

- Hand-written GPU code using CUDA

```
__global__ void
matmulKernel( float* C, float* A, float* B, int N2, int N3 ){
  int bx = blockIdx.x, by = blockIdx.y;
  int tx = threadIdx.x, ty = threadIdx.y;
  int aFirst = 16 * by * N2;
  int bFirst = 16 * bx;
  float Csub = 0;

  for( int j = 0; j < N2; j += 16 ){
    __shared__ float Atile[16][16], Btile[16][16];
    Atile[ty][tx] = A[aFirst + j * N2 * ty + tx];
    Btile[ty][tx] = B[bFirst + j * N3 + b * N3 * ty + tx];

    __syncthreads();

    for( int k = 0; k < 16; ++k )
      Csub += Atile[ty][k] * Btile[k][tx];

    __syncthreads();
  }

  int c = N3 * 16 * by + 16 * bx;
  C[c + N3 * ty + tx] = Csub;
}
```

Compiling for GPUs - Matrix Multiplication Example

- Hand-written CPU code using CUDA

```
void
matmul( float* A, float* B, float* C,
        size_t N1, size_t N2, size_t N3 ){
  void *devA, *devB, *devC;
  cudaSetDevice(0);

  cudaMalloc( &devA, N1*N2*sizeof(float) );
  cudaMalloc( &devB, N2*N3*sizeof(float) );
  cudaMalloc( &devC, N1*N3*sizeof(float) );

  cudaMemcpy( devA, A, N1*N2*sizeof(float), cudaMemcpyHostToDevice );
  cudaMemcpy( devB, B, N2*N3*sizeof(float), cudaMemcpyHostToDevice );

  dim3 threads( 16, 16 );
  dim3 grid( N1 / threads.x, N3 / threads.y );

  matmulKernel<<< grid, threads >>>( devC, devA, devB, N2, N3 );

  cudaMemcpy( C, devC, N1*N3*sizeof(float), cudaMemcpyDeviceToHost );
  cudaFree( devA );
  cudaFree( devB );
  cudaFree( devC );
}
```

Static (Leakage) Power

Di/Dt (Vdd/Gnd Bounce)

Code Optimizations for Low Power

- Most code optimizations reduce power use
 - Code executing fewer instructions use less power
- Other optimizations affect power, not performance
 - Reorder instructions
 - Reduce switching effect at functional units and I/O buses
 - Operand swapping
 - Swap the operands at the input of multiplier
 - Result is unaltered, but power changes significantly!
 - Use processor-specific instruction styles
 - On ARM the default int type is ~20% more efficient than char or short (sign/zero extension)
 - Use processor-specific features
 - Shut off unused registers to save power
 - Reduce voltage to save power when performance not needed
