Euterpea is an EDSL originally designed for synthesizing music. It is covered in the Haskell School of Music, a book which introduces basic music synthesis and functional programming at the same time. Euterpea provides the programmer a set of primitives, and a set of combinators which can form more complex structures.

```

- :=: is used for parallel composition (played at the same time)
- :+: is used for sequential composition (played one after the other).
- The dMinor below uses :=: to produce seventh chords.

```
t251' :: Music Pitch
t251' =
  let dMinor7 = d 3 hn :=: c 4 hn :=: c 5 hn :=:
    f 5 hn :=: c 6 hn
    gDom7 = g 3 hn :=: f 4 hn :=: b 4 hn :=:
        f 5 hn :=: b 5 hn
        cMajor7 = c 3 hn :=: b 3 hn :=: b 4 hn :=:
        e 5 hn :=: b 5 hn
    in dMinor7 :+: gDom7 :+: cMajor7
```

- :=: is used for parallel composition (played at the same time)
- :+: is used for sequential composition (played one after the other).
- The dMinor below uses :=: to produce seventh chords.
- We can assemble those chords with :+: to form the II-V-I Jazz progression.

▲□▶ ▲□▶ ▲□▶ ▲□▶ = ののの

Euterpea also introduces a few modifiers into the object language. Those modifiers, when interpreted, change the pitch or duration of the music.

- First, we construct a unidirectional arrow.

. . . . . . .

- In Agda, we need to distinguish between semantic and syntactic equivalence. To define the former, we need to define an equivalence relation.
- First, we construct a unidirectional arrow.
- Second, we wrap the unidirectional arrow with a symmetric closure, since we want the equality to go in both directions.

- In Agda, we need to distinguish between semantic and syntactic equivalence. To define the former, we need to define an equivalence relation.
- First, we construct a unidirectional arrow.
- Second, we wrap the unidirectional arrow with a symmetric closure, since we want the equality to go in both directions.
- Wrapping the symmetric closure with a transitive closure, and we obtain the equivalence relation we wanted.

• Given a Poset (not necessarily total order)  $\mathbb P$ 

<ロト </p>

- Given a Poset (not necessarily total order)  $\mathbb P$
- We define a new relation <> such that

$$a <> b \iff a < b \lor b < a$$

- Given a Poset (not necessarily total order)  $\mathbb P$
- We define a new relation <> such that

$$a <> b \iff a < b \lor b < a$$

• Intuitively, if  $a \ll b$  is true, we know that a and b are comparable.

Same as what we learned in class.

#### Definitions

```
data Primitive (A : Set) : Set where
Note : Dur \rightarrow A \rightarrow Primitive A
Rest : Dur \rightarrow Primitive A
```

```
data Music (A : Set) : Set where

Prim : (Primitive A) \rightarrow Music A

_:+:_ : Music A \rightarrow Music A \rightarrow Music A

_:=:_ : Music A \rightarrow Music A \rightarrow Music A

Modify : Control \rightarrow Music A \rightarrow Music A
```

### Definitions

```
data Primitive (A : Set) : Set where
Note : Dur \rightarrow A \rightarrow Primitive A
Rest : Dur \rightarrow Primitive A
```

```
data Music (A : Set) : Set where

Prim : (Primitive A) \rightarrow Music A

_:+:_ : Music A \rightarrow Music A \rightarrow Music A

_:=:_ : Music A \rightarrow Music A \rightarrow Music A

Modify : Control \rightarrow Music A \rightarrow Music A
```

Dur is a synonym of the set of natural numbers. While the set of natural numbers is clearly not a good representation of the duration, it has the nice semiring and lattice properties which will be handy in the proofs. Rational numbers share the same properties but they are not well-supported in the Agda standard library.

# **One-step Relation**

The relation music-step captures the basic algebraic properties of Music. We need to apply the EqClosure to support multiple-steps reasoning. The definition is mutually recursive because we want a more useful congruence axiom.

```
mutual
  data music-step : Music A \rightarrow Music A \rightarrow Set where
    tempo-mult : (r1 r2 : Dur) (m : Music A) \rightarrow
       music-step
         (Modify (Tempo r1) (Modify (Tempo r2) m))
         (Modify (Tempo ( r1 * r2 )) m)
    <code>trans-add</code> : (p1 p2 : AbsPitch) (m : Music A) \rightarrow
       music-step
         (Modify (Transpose p1) (Modify (Transpose p2) m))
         (Modify (Transpose ( p1 + p2 )) m)
```

### One-step Relation Cont.

```
-- . . .
   :+:-cong : {m m' n n' : Music A} \rightarrow
                  -- music-step m m' ?
                  \texttt{m} \approx \texttt{m'} \rightarrow
                  n \approx n' \rightarrow
                  music-step (m :+: n) (m' :+: n')
   :=:-cong : {m m' n n' : Music A} \rightarrow
                  \texttt{m} \approx \texttt{m'} \rightarrow
                  n \approx n' \rightarrow
                  music-step (m :=: n) (m' :=: n')
music-equiv : Rel (Music A) Level.zero
music-equiv = EqClosure music-step
private
  \approx = Setoid. \approx (setoid (music-step))
```

# Eliminating Rest 0

Rest 0 is essentially a neutral element in the algebra of Music. Some of them are redundant and can be optimized away. The function optimize-take2 (suggesting 1 failed attempt) eliminates all redundant Rest 0s. Clearly, the syntactic equality is no longer true, but that's the very reason why we defined the semantic equality  $_{\approx}$ . With the equivalence relation we defined, we can reason about the soundness of the optimization function.

```
optimize-take2 : (m : Music A) → Music A
optimize-take2 (Prim x) = Prim x
optimize-take2 (m :+: m1) with
   optimize-take2 m | empty-music? (optimize-take2 m)
optimize-take2 (m :+: m1)
   | .(Prim (Rest 0)) | yes empty = optimize-take2 m1
```

-- ... rest of the definition omitted

### Soundness Proof

```
optimize-sound-take2 : (m : Music A)
```

```
ightarrow (m pprox optimize-take2 m)
```

The soundness proof and the definition of optimization make extensive use of the view pattern:

```
data Empty-Music? : Music A \rightarrow Set where
empty : Empty-Music? (Prim (Rest 0))
```

```
<code>empty-music?</code> : (m : Music A) \rightarrow Dec (Empty-Music? m)
```

In the definition of the optimization function, we could use a catch-all pattern to simply the definition. However, Agda does not "remember" the catch-all pattern in the proofs which make use of the definition and would therefore require us to explicitly destruct all terms. The number of cases grows exponentially with respect to the number of parameters. The view pattern can mitigate the issue by reducing the base of the exponential function.

One extra property of the optimization function is idempotence. If the optimization invoked twice produces a result that is different from optimization invoked only once, that would imply our optimization is not exhaustive.

optimize-idempotent-take2 : (m : Music A) ightarrow

optimize-take2  $m \equiv$  optimize-take2 (optimize-take2 m) Note how the theorem switches from semantic equality we used for soundness proof to syntactic equality.
