Threads in Java

Department of Computer Science
University of Maryland, College Park
Problem

• Multiple tasks for computer
  • Draw & display images on screen
  • Check keyboard & mouse input
  • Send & receive data on network
  • Read & write files to disk
  • Perform useful computation (editor, browser, game)
• How does computer do everything at once?
  • Multitasking
  • Multiprocessing
Multitasking (Time-Sharing)

• **Approach**
  • Computer does some work on a task
  • Computer then quickly switch to next task
  • Tasks managed by operating system (scheduler)

• **Computer seems** to work on tasks concurrently
• Can improve performance by reducing waiting
Multitasking Can Aid Performance

- Single task

- Two tasks

Total Execution Time = 7 seconds

Total Time Executing Code: 4 seconds
Total Time Waiting: 3 seconds
Time Executing Code: 57%  Time Waiting: 43%

Total Time Executing Code: 8 seconds
Total Time Waiting: 0 seconds
Time Executing Code: 100%  Time Waiting: 0%
Multiprocessing (Multithreading)

- Approach
  - Multiple processing units (multiprocessor)
  - Computer works on several tasks in parallel
  - Performance can be improved

Dual-core AMD Athlon X2
32 processor Pentium Xeon
4096 processor Cray X1

Beowulf computer cluster (Borg, 52-node cluster used by McGill University Image/Info from Wikipedia)
Perform Multiple Tasks Using Processes

- Process
  - Definition → executable program loaded in memory
  - Has own address space
    - Variables & data structures (in memory)
  - Each process may execute a different program
  - Communicate via operating system, files, network
  - May contain multiple threads
Perform Multiple Tasks Using **Threads**

• **Thread**
  • Definition → sequentially executed stream of instructions
  • Has own **execution context**
    • Program counter, call stack (local variables)
  • Communicate via shared access to data
  • Also known as “lightweight process”
  • Let’s see how memory is organized for a threaded environment
  • **Diagram**
Motivation for Multithreading

- Captures logical structure of problem
  - May have concurrent interacting components
  - Can handle each component using separate thread
  - Simplifies programming for problem

- Example

Web Server uses threads to handle …

Multiple simultaneous web browser requests
Motivation for Multithreading

• Better utilize hardware resources
  • When a thread is delayed, compute other threads
  • Given extra hardware, compute threads in parallel
  • Reduce overall execution time

• Example

Multiple simultaneous web browser requests... Handled faster by multiple web servers
Programming with Threads

• Concurrent programming
  • Writing programs divided into independent tasks
  • Tasks may be executed in parallel on multiprocessors

• Multithreading
  • Executing program with multiple threads in parallel
  • Special form of multiprocessing
Creating Threads in Java

• Two approaches to create threads
  • Extending Thread class (NOT RECOMMENDED)
  • Runnable interface approach (PREFERED)

• Approach 1: Extending Thread class
  • We overload the Thread class run() method
  • The run() methods defines the actual task the thread performs
  • Example
    
    ```java
    public class MyT extends Thread {
        public void run() {
            ...
            // work for thread
        }
    }
    ```
    MyT t = new MyT(); // create thread
t.start(); // begin running thread
...
  // thread executing in parallel
• Example: message, messageThreadExtends packages
Creating Threads in Java

- **Approach 2: Runnable Interface**
  - Define a class (worker) that implements the Runnable interface
    ```java
    public interface Runnable {
        public void run();  // work done by thread
    }
    ```
  - Create thread to execute the run() method
    - Alternative 1: Create thread object and pass worker object to Thread constructor
    - Alternative 2: Hand worker object to an executor
  - Example
    ```java
    public class Worker implements Runnable {
        public void run() {
            // work for thread
        }
    }
    ```
    ```java
    Thread t = new Thread(new Worker());  // create thread
    t.start();  // begin running thread
    ```
  - **Example:** message, messageThreadRunnable packages
Why Extending Thread Approach Not Recommended?

- Not a big problem for getting started
  - But a bad habit for industrial strength development
- Methods of worker and Thread class intermixed
- Hard to migrate to more efficient approaches
  - Thread Pools
Thread Class

public class Thread extends Object implements Runnable {
  public Thread();
  public Thread(String name); // Thread name
  public Thread(Runnable R);
  public Thread(Runnable R, String name);

  public void run(); // if no R, work for thread
  public void start(); // thread gets in line so it eventually it can run
  ...
}
public class Thread extends Object {
    ...
    public static Thread currentThread()
    public String getName()
    public void interrupt()  // alternative to stop (deprecated)
    public boolean isAlive()
    public void join()
    public void setDaemon()
    public void setName()
    public void setPriority()
    public static void sleep()
    public static void yield()
}
Creating Threads in Java

• Note
  • Thread eventually starts executing **only if start() is called**

• Runnable is interface
  • So it can be implemented by any class
  • Required for multithreading in applets

• **Do not call the run method directly**
Threads – Thread States

- Java thread can be in one of these states
  - **New** → thread allocated & waiting for start()
  - **Runnable** → thread can begin execution
  - **Running** → thread currently executing
  - **Blocked** → thread waiting for event (I/O, etc.)
  - **Dead** → thread finished

- Transitions between states caused by
  - Invoking methods in class Thread
    - `new()`, `start()`, `yield()`, `sleep()`, `wait()`, `notify()`…
  - Other (external) events
    - Scheduler, I/O, returning from run()…

- In Java states defined by `Thread.State`
  - [Java Thread States](http://docs.oracle.com/javase/6/docs/api/java/lang/Thread.State.html)
Threads – Thread States

- State diagram

Running is a logical state → indicates runnable thread is actually running
