Introduction to Functions

- Function - An entity that completes a particular task for us.
- It can takes values necessary to complete a particular task.
- It can return values.
- After completing a task it returns to the point after the call.
- Examples of JavaScript functions.
 - document.writeln
 - alert()
- You can define your own functions.
- **Example:** Function.html

Introduction to Functions

- General form of a function is:

```
function name (<comma-separated list of parameters>)  
{  
    statements  
}
```

- Functions are invoked by using the () operator.
- A function can receive values via parameters.
- Some functions may not return a value.
- Some functions may not take any parameters.
- There are other approaches to define functions.

main() Function

- The organization for code dealing with functions will be as specified in the following example.
- **Example:** MainFunction.html

JavaScript (Functions)

- Advantages of functions are:
 - Allows you factor out common code.
 - Allows you to reuse code.
 - Allows you to control the code complexity.
- While designing a solution to a problem you can divide a problem into sub-problems each represented by a function.

Passing Values to Function

- Mechanism used to pass values to function is called pass-by-value
- Parameters – variables in the function that receive data
 - There are normal variables
- Arguments – values you pass to a function
- **Example:** PassingValues.html
- Does it matter how we name the parameters?

Functions Returning Values

- A function can return a value via the return statement
return expression;
- A call to a function that returns a value can be used as an expression
- **Example:** (See FunctionReturn.html)
- The function execution terminates when a return statement is executed
- A return statement with no return value terminates the function execution
- Can we return more than one value?

Scope of Variables

- Variables declared in a function are called local variables
- They are created on entry to the function and destroy on exit
- You can use the same name in different functions as they are different variables
- Variables declared outside of a function are called global variables.

Generation of Random Values

- Example: RandomValues.html

Events

- **Event** – Notification that something has occurred
- Example of situations that make the web browser generate an event
 - Browser finishes loading a document
 - When the user clicks on a button
 - When the user moves the mouse
 - Others
- **Event handler** (also known as event listener)
 - JavaScript function or code fragment that is executed when a particular event occurs
- **Event handler registration**
 - Associating an event handler with a particular event
- **Example:** EventEx.html

Event-driven Programming

- **Normal (control flow-based) programming**
 - Approach
 - Start at main()
 - Continue until end of program or exit()
- **Event-driven programming**
 - Start at main()
 - Register event handlers
 - Await events & perform associated computation
- **GUIs (Graphical User Interfaces)**
 - Example of event-driven software

Event Handler Attributes for most HTML

■ Mouse Related

- ❑ **onclick** – mouse button is pressed and released
- ❑ **ondblclick** – mouse button is double-click over element
- ❑ **onmouseover** – mouse moves over element
- ❑ **onmouseout** – mouse moves off element
- ❑ **onmousemove** – mouse pointer is moved
- ❑ **onmousedown** – mouse is pressed down while cursor is over the element
- ❑ **onmouseup** – mouse is released while the cursor is over the element

■ Keyboard Related

- ❑ **onkeypress** – key pressed and released
- ❑ **onkeydown** – key is pressed
- ❑ **onkeyup** – key is released

■ Other

- ❑ Keep in mind that there additional handlers that are specific to certain tags. We will address those later on

For Loop

- Iteration statement
- General form

*for (initialize; test; expression)
statement*

basically equivalent to

*Initialize
while (test) {
statement
expression
}*

If more than one statement use { }

- **Example:** ForLoops.html
- **Example:** ForLoopVariations.html

Arrays

- **Problem** - You need to keep track of the scores of students in a class
 - Declaring and handling 50 variables is not an easy task
 - Arrays come to the rescue
- **Array** – Collection of values that can be treated as a unit or individually.
- You can visualize an array as a set of variables one after another
- There are several ways to define arrays.

```
var scienceScores = new Array(); // Creates an empty array  
var mathScores = new Array(3); // Creates an array with 3 entries  
var englishScores = [77, 88, 65]; // Creates an array with 3 entries  
// having the specified
```

values

Arrays

- To access elements of an array
 - Use the [] operator
 - We will use index values **starting at zero** to represent each element
- Accessing array elements

```
mathScores[0] = 70; // Assigning 70 to the first array element  
mathScores[1] = 80; // Assigning 80 to the second array element  
var total = mathScores[0] + mathScores[1]; // reading the first  
// and second elements
```

- The array length property defines the number of elements
- Several functions are associated with arrays.
 - `sort()` – sorts elements of an array
 - `reverse()` – reverse elements of an array
 - `join()` – converts elements of an array to string and concatenates them
 - Others
- For loops are frequently use to iterate through arrays
- **Example:** ArrayEx.html
