

# Toward a Theory of Encoded Data Structures and Data Translation

Ben Shneiderman<sup>1</sup> and Stuart C. Shapiro<sup>1</sup>

*Received March 1975; revised June 1975*

---

Several models of data base systems have distinguished levels of abstraction ranging from the high-level entity set model down to the low-level physical device level. This paper presents a model for describing data encodings, an intermediate level which focuses on the relationship among data items as demonstrated by contiguity or by pointer connections. Multiple data encodings for a file are shown and transformation functions that describe the translation between data encodings are discussed.

---

**KEY WORDS:** Data encoding; data translation; data base systems; data description.

## 1. INTRODUCTION

Numerous attempts have been made to develop a theoretical foundation for describing data base systems. Recent work has suggested a multileveled approach which clearly separates the logical aspects from the physical aspects.

The well-thought-out DIAM model<sup>(1)</sup> provides a comprehensive four-level view of data base systems. The highest level, the *entity set model*, reflects the user's view of the data and is heavily influenced by Codd's work<sup>(2)</sup> on the relational model. The next level, the *string model*, describes the logical access path structure and draws heavily on graph-theoretic notions.<sup>(3,4)</sup> More closely related to the implementation details is the *encoding model*, which focuses on the internal representation and encoding of storage structures. Finally, the *physical device model* deals with the placement of encoded data on the physical storage media.

---

<sup>1</sup> Department of Computer Science, Indiana University, Bloomington, Indiana.

Earley's work<sup>(6,6)</sup> distinguishes relational level, access path level, and an implementation level. He envisions programming languages at each level and the progression through stepwise refinement from abstract to concrete algorithms.<sup>(7)</sup> The lower-level languages enable the user to carefully specify more implementation details, with the goal of improving efficiency.

Child's early work<sup>(8)</sup> on set-theoretic models to describe the high-level logical view has been supplemented by work on extended set theory<sup>(9)</sup> to describe the implementation details.

These multilevel approaches provide useful divisions for dealing with the complexity of a sophisticated data base system. Psychologists can be employed to assist in the selection of high-level models and languages, while experts in the operation of physical devices can focus their attention on the machine-oriented aspects.

## 2. MAPPING THE ENTITY SET MODEL INTO DATA ENCODINGS

This paper addresses the problem of describing the static relationships among data and provides the basis for mappings that describe the translation from one data encoding to another. The dynamics of insertion, deletion, and updating are beyond the scope of this work.

We adopt the abstract perspective that the entity set model can be mapped into one or more data encodings. Each of these mappings is an *implementation* of the logical view of the data (see Fig. 1), that is,  $I: \hat{L} \rightarrow \hat{E}$ , where  $I$  is the implementation,  $\hat{L}$  is the space of logical data structures, and  $\hat{E}$  is the space of data encodings.

To clarify this basic notion, consider a one-way list. The implementation might be by a linked list strategy within the high-speed storage, by a linked list stretching over several disk blocks, by contiguous allocation within a block, by contiguous allocation plus links to overflow blocks, and so on. For a more complex case, consider the logical view put forth by Codd's

$$I: \hat{L} \rightarrow \hat{E}$$

Fig. 1

relational model. A number of widely varying implementations can be envisioned for this logical view.

While a number of formulations have been proposed for dealing with the logical view of data structures, there is a dearth of techniques for describing data encodings produced by a specific implementation. Although the present model does not completely describe the machine level details, it does serve as an intermediate descriptive model.

### 3. THE MODEL

The basic components of a *data encoding* are *blocks*. A block is an addressable, contiguous segment of storage. A block is divided into *elements*, each of which is *field* or a block. A field is a contiguous segment of storage and is the smallest meaningful unit of a data encoding. There are two kinds of fields: *data fields* and *pointer fields*. The contents of a data field are *data items*; each data item is an encoding of some piece of information from the entity set model. The contents of a pointer field are *pointers*; each pointer addresses a block. For example,  $[f_1, f_2, f_3, f_4]$  represents four fields in a single block which are contiguous in the specified sequence, and  $[[f_1, f_2], [f_3, f_4]]$  represents a block consisting of two contiguous subblocks, each of which contains two fields.

*Definition 1.* We define how blocks may be constructed from fields. Let  $\Lambda$  be the null block. Let  $F$  be some set of fields. We now define  $\bar{B}_F$ , which is the set of blocks using the fields in  $F$ .  $\bar{B}_F$  does not include  $\Lambda$ .

(i) If  $f_1, \dots, f_n$  for  $n \geq 1$  are in  $F$ , then  $[f_1, \dots, f_n]$  is in  $\bar{B}_F$ . This shows how fields can be combined to form a block.

(ii) If  $e_1, \dots, e_n$  for  $n > 1$  are in  $F$  or in  $\bar{B}_F$ ,  $[e_1, \dots, e_n]$  is in  $\bar{B}_F$ . This shows how blocks and fields may be combined to form a block. Note that a block that contains only a block is not valid.

(iii) That is all that is in  $\bar{B}_F$ .

Now, let  $\hat{B}_F = \bar{B}_F \cup \{\Lambda\}$ .  $\hat{B}_F$  is the set of all blocks that can be constructed from the fields in  $F$  plus the null block.

If  $b = [e_1, \dots, e_n]$  is in  $\hat{B}_F$ , we call  $e_i$ ,  $1 \leq i \leq n$ , the *elements* of  $b$ . We will want to talk about the number of elements in a block.

*Definition 2.* If  $b = [e_1, \dots, e_n]$  is in  $\hat{B}_F$  for some  $F$ , then  $|b|_e = n$ .

We will also need projection functions which select an element from a block.

*Definition 3.* If  $b = [e_1, \dots, e_n]$  is in  $\hat{B}_F$  for some  $F$  and  $1 \leq i \leq n$ , then  $\pi_i(b) = e_i$ .

**Definition 4.** We will use the symbol  $[\![_{i=1}^n]$  for a sequence in the same way that  $\sum_{i=1}^n$  is used for a sum. Thus,  $[\![_{i=1}^n e_i]$  is the same as  $[e_1, \dots, e_n]$ .

To describe a particular data encoding  $E$  we must describe:

1.  $D$ , the set of data fields.
2.  $P$ , the set of pointer fields (sometimes empty).
3.  $B$ , the set of blocks.  $B$  will be subset of  $\hat{B}_{D \cup P}$ .
4.  $g$ , a function from  $P$  into  $B$ , which describes the pointer relationships among the blocks.

#### 4. EXAMPLES OF DATA ENCODINGS

At this point a clarifying example to contrast four possible implementations is useful. Consider the representation of a file  $a$  consisting of records  $b_i$ , where  $1 \leq i \leq N$ , which in turn consist of a student number field  $d_{i0}$  and three exam grade fields:  $d_{i1}$ ,  $d_{i2}$ , and  $d_{i3}$ .

(A) The first implementation shows the records to be arranged sequentially with contiguous fields within each record (see Fig. 2a):

$$\begin{aligned} D &= \{d_{ij} \mid 1 \leq i \leq N, \quad 0 \leq j \leq 3\} \\ P &= \emptyset, \text{ the empty set} \\ B &= \{a\} \cup \{b_i \mid 1 \leq i \leq N\} \\ a &= [\![_{i=1}^N b_i], \text{ i.e., } |a|_e = N \text{ and } \pi_i(a) = b_i \end{aligned}$$

For each  $i$ ,  $1 \leq i \leq N$ ,

$$b_i = [d_{i0}, d_{i1}, d_{i2}, d_{i3}]$$

i.e.,  $|b_i|_e = 4$  and for  $0 \leq j \leq 3$ ,  $\pi_{j+1}(b_i) = d_{ij}$ .  $g$  is empty.

(B) The second implementation shows each record as a one-way list. The records are sequentially arranged (see Fig. 2b):

$$\begin{aligned} D &= \{d_{ij} \mid 1 \leq i \leq N, \quad 0 \leq j \leq 3\} \\ P &= \{p_{ij} \mid 1 \leq i \leq N, \quad 0 \leq j \leq 3\} \\ B &= \{a\} \cup \{b_{ij} \mid 1 \leq i \leq N, \quad 0 \leq j \leq 3\} \cup \{A\} \end{aligned}$$

For  $1 \leq i \leq N$ ,  $0 \leq j \leq 3$ , and  $0 \leq k \leq 2$ ,

$$\begin{aligned} a &= [\![_{i=1}^N b_{i0}], \quad |a|_e = N, \quad \pi_i(a) = b_{i0} \\ b_{ij} &= [d_{ij}, p_{ij}], \quad |b_{ij}|_e = 2, \quad \pi_1(b_{ij}) = d_{ij}, \quad \pi_2(b_{ij}) = p_{ij} \\ g(p_{ik}) &= b_{i(k+1)}, \quad g(p_{i3}) = A \end{aligned}$$

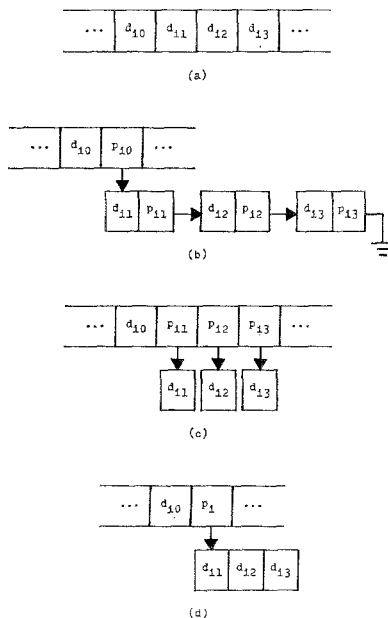

Fig. 2

(C) The third implementation is by the use of the pointer array technique for the grades within each record (see Fig. 2c):

$$D = \{d_{ij} \mid 1 \leq i \leq N, \ 0 \leq j \leq 3\}$$

$$P = \{p_{ik} \mid 1 \leq i \leq N, \ 1 \leq k \leq 3\}$$

$$B = \{a\} \cup \{b_i \mid 1 \leq i \leq N\} \cup \{c_{ik} \mid 1 \leq i \leq N, \ 1 \leq k \leq 3\}$$

$$a = [||_{i=1}^N b_i]$$

For  $1 \leq i \leq N, 0 \leq j \leq 3,$  and  $1 \leq k \leq 3,$

$$\begin{aligned} |a|_e &= N, & \pi_i(a) &= b_i \\ b_i &= [d_{i0}, p_{i1}, p_{i2}, p_{i3}] \\ |b_i|_e &= 4, & \pi_1(b_i) &= d_{i0}, & \pi_{k+1}(b_i) &= p_{ik} \\ c_{ik} &= [d_{ik}], & |c_{ik}|_e &= 1, & \pi_1(c_{ik}) &= d_{ik} \\ g(p_{ik}) &= c_{ik} \end{aligned}$$

(D) The fourth implementation simply splits the first data field in each record from the remaining three (see Fig. 2d):

$$D = \{d_{ij} \mid 1 \leq i \leq N, \ 0 \leq j \leq 3\}$$

$$P = \{p_i \mid 1 \leq i \leq N\}$$

$$B = \{a\} \cup \{b_i \mid 1 \leq i \leq N\} \cup \{c_i \mid 1 \leq i \leq N\}$$

For  $1 \leq i \leq N$ , and  $1 \leq k \leq 3$ ,

$$\begin{aligned}
 a &= [\prod_{i=1}^N b_i], & |a|_e &= N, & \pi_i(a) &= b_i \\
 b_i &= [d_{i0}, p_i], & |b_i|_e &= 2, & \pi_1(b_i) &= d_{i0}, & \pi_2(b_i) &= p_i \\
 c_i &= [d_{i1}, d_{i2}, d_{i3}], & |c_i|_e &= 3, & \pi_k(c_i) &= d_{ik} \\
 g(p_i) &= c_i
 \end{aligned}$$

A final example describes the DBTG Report concept of a set implemented by chain with next and prior pointers. The set  $S$  consists of an owner record with three data fields,  $r$ ,  $s$ , and  $t$ , and  $N$  member records each with two data fields,  $u$  and  $v$  (see Fig. 3):

$$\begin{aligned}
 D &= \{r, s, t\} \cup \{u_i, v_i \mid 1 \leq i \leq N\} \\
 P &= \{n_i, p_i \mid 0 \leq i \leq N\} \\
 B &= \{a\} \cup \{b_i \mid 1 \leq i \leq N\} \\
 a &= [r, s, t, n_0, p_0], & |a|_e &= 5 \\
 \pi_1(a) &= r, & \pi_2(a) &= s, & \pi_3(a) &= t, & \pi_4(a) &= n_0, & \pi_5(a) &= p_0
 \end{aligned}$$

For  $1 \leq i \leq N$ ,

$$\begin{aligned}
 b_i &= [u_i, v_i, n_i, p_i], & |b_i|_e &= 4 \\
 \pi_1(b_i) &= u_i, & \pi_2(b_i) &= v_i, & \pi_3(b_i) &= n_i, & \pi_4(b_i) &= p_i \\
 g(n_i) &= \begin{cases} b_{i+1}, & 0 \leq i < N \\ a, & i = N \end{cases} \\
 g(p_i) &= \begin{cases} b_{i-1}, & 1 < i \leq N \\ a, & i = 1 \\ b_N, & i = 0 \end{cases}
 \end{aligned}$$

Fig. 3

## 5. PRESCRIPTIVE MODEL

The descriptive model presented thus far is useful as a formal tool for communication among implementers and serves as a basis for a component of the total data description task. Such data description facilities are needed by those attempting to improve data structure implementations,<sup>(11,12)</sup> create data base systems simulators,<sup>(13,14)</sup> and construct data translation systems.<sup>(15,22)</sup>

The data translation paradigm is to develop a description of source and target data encodings and a procedural translation facility to describe the mapping. We elaborate on the data encoding model by adding transformation functions which describe translations from one data encoding to another.

Keep in mind that the prescriptive model describes the relationship between a source and a target data encoding; it is not a program for doing the translation.

In the following definitions,  $E$  is some particular data encoding.

*Definition 5.* If  $d$  is a piece of information from some data that  $E$  encodes,  $\text{encode}_E(d)$  is the data item in  $E$  that encodes  $d$ . Recall that data items are the contents of a data field.

*Definition 6.* If  $f$  is a data field in  $E$ ,  $\text{meaning}_E(f)$  is the meaning of the contents of  $f$ . That is,  $\text{encode}_E(\text{meaning}_E(f))$  is the data item that is the content of the data field  $f$ .

*Definition 7.* If  $f$  is a data field in a data encoding  $E'$  such that  $E'$  encodes the same data as  $E$ ,  $\text{trans}_{E'E}(f) = \text{encode}_E(\text{meaning}_{E'}(f)) =$  the translation into  $E$  of the contents of  $f$ .

*Definition 8.* If  $b$  is a block in  $E$ ,  $\text{ref}_E(b)$  is a pointer to  $b$ . If  $p$  is a pointer to  $b$ ,  $\text{fer}_E(p) = b$ .

*Definition 9.* If  $f$  is a data field in  $E$ ,  $\text{val}_E(f)$  is the data item contained in  $f$ . If  $p$  is a pointer field in  $E$ ,  $\text{val}_E(p)$  is the pointer contained in  $p$ . If  $b$  is a block in  $E$ ,  $\text{val}_E(b) = b$ . Note: If  $p$  is a pointer field in  $E$ ,  $g(p) = \text{fer}_E(\text{val}_E(p))$ . If  $b$  is a block in  $E$  and  $p_1$  and  $p_2$  both point to  $b$ ,  $\text{val}_E(p_1) = \text{val}_E(p_2) = \text{ref}_E(b)$ .

*Definition 10.* If  $e_1, \dots, e_n$  are data items, pointers, or blocks in  $E$ , then  $\text{cons}_E(e_1, \dots, e_n)$  is a block  $b$  in  $E$  such that  $\text{val}_E(\pi_i(b)) = e_i$ . That is,  $b = [f_1, \dots, f_n]$ , where for  $1 \leq i \leq n$ ,  $\text{val}_E(f_i) = e_i$ .

We will now show how data encodings (A)–(D) above are related. In what follows, we will use superscripts to show what data encoding is being

used. We will show how to derive (B) from (A), (C) from (B), (D) from (C), and (A) from (D).

(A)  $\rightarrow$  (B).  $N^B = N^A = N$ . For  $1 \leq i \leq N$  and  $0 \leq j \leq 3$ ,  $\text{meaning}_B(d_{ij}^B) = \text{meaning}_A(d_{ij}^A)$ . We have

$$\begin{aligned} b_{i4}^B &= A \\ b_{ij}^B &= \text{cons}(\text{trans}_{AB}(\pi_{j+1}(\pi_i(a^A))), \text{ref}(b_{ij+1}^B)) \\ a^B &= \text{cons}(\|_{i=1}^N b_{i0}^B) \end{aligned}$$

(B)  $\rightarrow$  (C).  $N^C = N^B = N$ . For  $1 \leq i \leq N$  and  $0 \leq j \leq 3$ ,

$$\begin{aligned} \text{meaning}_C(d_{ij}^C) &= \text{meaning}_B(d_{ij}^B) \\ a^C &= \text{cons}(\|_{i=1}^{N^B} \text{cons}(\text{trans}_{BC}(\pi_1(\pi_i(a^B))), \\ &\quad \text{ref}_C(\text{cons}_C(\text{trans}_{BC}(\pi_1(g^B(\pi_2(\pi_i(a^B)))))), \\ &\quad \text{ref}_C(\text{cons}_C(\text{trans}_{BC}(\pi_1(g^B(\pi_2(g^B(\pi_2(\pi_i(a^B))))))), \\ &\quad \text{ref}_C(\text{cons}_C(\text{trans}_{BC}(\pi_1(g^B(\pi_2(g^B(\pi_2(g^B(\pi_2(\pi_i(a^B))))))))))))))))) \end{aligned}$$

(C)  $\rightarrow$  (D).  $N^D = N^C = N$ . For  $1 \leq i \leq N$  and  $0 \leq j \leq 3$ ,

$$\begin{aligned} \text{meaning}_D(d_{ij}^D) &= \text{meaning}_C(d_{ij}^C) \\ a^D &= \text{cons}_D(\|_{i=1}^{N^C} \text{cons}(\text{trans}_{CD}(\pi_1(\pi_i(a^C))), \\ &\quad \text{ref}_D(\text{cons}_D(\text{trans}_{CD}(\pi_1(g^C(\pi_2(\pi_i(a^C)))))), \\ &\quad \text{trans}_{CD}(\pi_1(g^C(\pi_3(\pi_i(a^C))))), \\ &\quad \text{trans}_{CD}(\pi_1(g^C(\pi_4(\pi_i(a^C))))))))) \end{aligned}$$

(D)  $\rightarrow$  (A).  $N^A = N^D = N$ . For  $1 \leq i \leq N$  and  $0 \leq j \leq 3$ ,

$$\begin{aligned} \text{meaning}_A(d_{ij}^A) &= \text{meaning}_D(d_{ij}^D) \\ a^A &= \text{cons}(\|_{i=1}^{N^D} \text{cons}(\text{trans}_{DA}(\pi_1(\pi_i(a^D))), \\ &\quad \text{trans}_{DA}(\pi_1(g^D(\pi_2(\pi_i(a^D))))), \\ &\quad \text{trans}_{DA}(\pi_2(g^D(\pi_2(\pi_i(a^D))))), \\ &\quad \text{trans}_{DA}(\pi_3(g^D(\pi_2(\pi_i(a^D)))))) \end{aligned}$$

*Strong Equivalence*

Two encodings are strongly equivalent if they have the same block structure, pointer structure, and the value of each of the data fields in one encoding is equal to the value of the corresponding data fields in the other encoding. Thus two copies of a record on the same or a different disk pack are strongly equivalent.

*Weak Equivalences*

Two encodings are weakly equivalent if they have the same block structure and pointer structure but the values of the data fields differ in value. Thus, two DBTG record occurrences of the same DBTG record type are weakly equivalent. If the fields had identical values, the records would be strongly equivalent.

**6. ENHANCEMENTS TO THE DESCRIPTIVE MODEL**

This basic descriptive notation can be enhanced in numerous ways. To evaluate the efficiency of a particular encoding, a cost function can be associated with each pointer,  $C: P \rightarrow T$ , where  $C$  is the cost function,  $P$  is the set of pointers, and  $T$  is the cost, typically in units of time or money. The cost of traversing a pointer within a block is generally less than inter-block traversals. The contiguous fields within a block are assumed to be available at zero cost. A probability of request may be associated with each field to further refine the evaluative model.

The storage space required can be determined by a simple count of the number of fields. We write  $|b|_f$  to indicate the number of fields in a block.  $|f|_f = 1$  if  $f$  is in  $F$ , and if  $b = [e_1 \cdots e_n]$ , then  $|b|_f = \sum_{i=1}^n |e_i|_f$ .

To attach more meaning to the fields, that is, to provide an interpretation for the abstract encoded data structure, a value function can be invoked. For example, to show that data fields  $d_{10} \cdots d_{N0}$  are in ascending order, we write

$$\text{val}(d_{i0}) \leq \text{val}(d_{i+1,0}), \quad 1 \leq i \leq N$$

Finally, we may consider inclusion of undefined fields. An undefined field is different from a null pointer field. Undefined fields are useful in describing space in a block that has been reserved for future entries. This allows for descriptions of partially filled tables or available space lists which contain pointer fields and undefined fields. Garbage collection, compaction, and reorganization become special kinds of translations.

## 7. CONCLUSION

The material in this paper provides the basis for developing a model of encoded data structures. The fundamental motive has been to characterize the contiguous and pointer-based relationship among fields in a storage facility. The model avoids issues related to physical devices and the details of pointer implementation, such as whether pointers indicate absolute or relative storage addresses or disk region addresses.

Other data description models pursue a more reductionist approach: Starting from high-level logical data constructs, they show how these constructs might be represented in the storage space. Our constructive approach to data description starts with a more precise low-level view and seeks to carefully model the data as they appear in the storage space. This more formal approach distinguishes between data fields and their contents, the data items.

The model serves as a useful basis for describing part of the data translation task. The source and target data encodings can be described and then the prescriptive model can be used to show the relationship between them.

We have not attempted to present a language or operators for data translation, but a prescriptive model which formally demonstrates a mapping between two data descriptions. This formal model is necessary if we are to prove the correctness of a translation and to show that no information has been lost.

Further investigations are proceeding to describe hierarchically organized collections, implicit pointer techniques such as hash coding, and specific transformations such as the permutation of elements in a block or the replacement of a block by a pointer.
