Announcements

- Reading Chapter 19
- MT#2 re-grade requests due by end of class

Computer Threat Model

- must consider acceptable risks
 - value of item to be protected
 - \$2,000 of computer time to steal 50 cents of data
 - this is a sufficient deter someone
 - but computers keep getting faster
- Basic Ideas:
 - confine access to only the highest level needed
 - run programs as root only if needed
 - don't give system access to all users

Authentication

- How does the computer know who is using it?
 - need to exchange some information to verify the user
 - types of information exchanged:
 - pins
 - numeric passwords
 - too short to be secure in most cases
 - passwords
 - a string of letters and numbers
 - often easy to guess
 - challenge/response pairs
 - user needs to be apply to apply a specific algorithm
 - often involve use of a calculator like device
 - can be combined with passwords
 - unique attributes of the person
 - i.e. signature, thumb print, DNA?
 - sometimes these features can change during life

Authentication (cont.)

- How does a user know what computer they are using?
- Need to have mutual authentication
 - computer presents some information that only it could contain
 - example: Windows <ctrl>-<alt>- to login
 - user software can't trap that information
 - assumes that the kernel itself is secure
- telephone example:
 - never give banking/credit card info over the phone unless you placed the phone call
 - i.e. you use the telco namespace for authentication

Example (UNIX passwords) use a function that is hard to invert

- - "easy" to compute f(x) given x
 - hard to compute x given f(x)
 - the function used is a variation on the DES algorithm
 - changes selected items in the transformation matrix to prevent hardware attacks
 - store only f(x) in the filesystem
- to login:
 - user supplies a password x'
 - compute f(x') and compare to f(x)
- salt
 - add an extra two characters to x so that the same x will produce different values on different machines
- dictionary attach
 - if its to easy to compute f(x)
 - can "guess" many passwords and try them out

Types of Software Threats

Trojan Horse

- a program that looks like a normal program
- for example a login program written by a user
- UNIX example: never put "." early in your path

Trap door

- hole left by the programmers to let them into the system
- "system" password set to a default value by the vendor

Worms

- programs that clone themselves and use resources
- Internet worm:
 - exploited several bugs and "features" in UNIX
 - .rhosts files
 - bug in finger command (overwrite strings)
 - sendmail "debug" mode to run commands

Viruses

- Most common on systems with little security
 - easy to write to boot blocks, system software
 - never run untrusted software with special privileges
 - Don't perform daily operations with root/system privileges
- Possible to write system independent viruses
 - MS Word virus
 - uses macros to call into the OS

Access Matrix

- Abstraction of protection for objects in a system.
 - Rows are domains (users or groups of users)
 - Columns are objects (files, printers, etc.)
 - Items are methods permitted by a domain on an objects
 - read, write, execute, print, delete, ...
- Representing the Table
 - simple representation (dense matrix) is large
 - sparse representation possible: each non-zero in the matrix
 - observation: same column used frequently
 - represent groups of users with a name and just store that
 - create a default policy for some objects without a value
- Revocation of access
 - when are access rights checked?
 - selective revocation vs. global

Access Matrix

	F1	F2	F3	Laser Printer	
D1	read		execute		
D2			execute	print	
D3	read, write		execute		
D4			execute		
D5		delete			

- Rows represent users or groups of users
- Columns represent files, printers, etc.

Capabilities

- Un-forgeable Key to access something
- Implementation: a string
 - I.e. a long numeric sequence for a copier)
- Implementation: A protected memory region
 - tag memory (or procedures) with access rights
 - example x86 call gate abstraction
 - permit rights amplification
