

## Structure-from-Motion: Perspective

- We'll just consider two images.
- Known cameras, perspective projection.
- Known corresponding points in each image.
- Want to recover relative position of cameras, 3D position of points.
- Given camera position, point recovery is just like stereo.

## Strategy: Focus on Epipolar Geometry

- Recall from stereo, images have matching lines.
  - All points on line in one image match some point on matching line in other image.
  - Which lines match depends on relative camera positions.
- We use matching points to find matrix,  $E$ , that encodes epipolar lines.
  - This can also be useful to find more matching points.
- Once we have  $E$ , we can find relative camera positions.

## So first, recall epipolar geometry

Consider plane through two focal points.

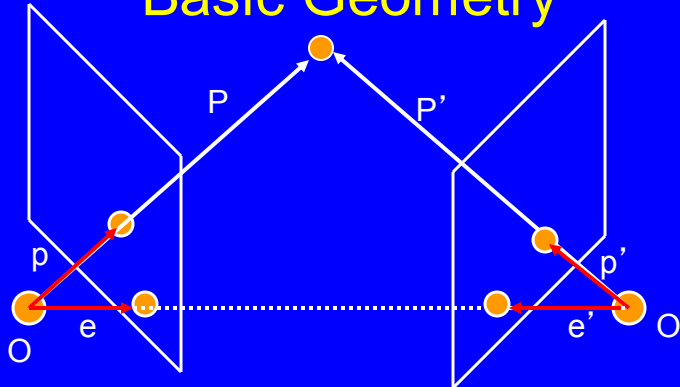

Projects to line in each image.

All points in world are on one of these planes.

## Epipole

- Consider line through focal points.
  - All these planes contain this line.
  - This line intersects each image plane in epipole.
  - Every pair of epipolar lines has to go through these epipoles.
- Epipoles depend on direction of translation.

## Basic Geometry

Relationship between images is translation,  $T$ , and rotation,  $R$ .

$$T = (O' - O) \quad P' = R^T(P - T)$$

## Key Point about Epipoles

- The *Essential* matrix,  $E$ 
  - $p'^T E p = 0$
  - Given either point, we have a linear equation in the other.
  - Questions are: how exactly do we get this, and what is relation between  $E$  and motion?

## Digression: Representing coplanarity

Suppose  $U$  and  $V$  are unit vectors. Let  $W$  be a unit vector that is perpendicular to both of them. We write:

$W = U \times V$ . We can write:

$$W = \begin{pmatrix} 0 & -U_z & U_y \\ U_z & 0 & -U_x \\ -U_y & U_x & 0 \end{pmatrix} V$$

To verify this, consider  
 $V^T W = V_x(-U_z V_y + U_y V_z) +$   
 $V_y(U_z V_x - U_x V_z) + V_z(-$   
 $U_y V_x + U_x V_y) = 0$

$U^T W = U_x(-U_z V_y + U_y V_z) +$   
 $U_y(U_z V_x - U_x V_z) + U_z(-$   
 $U_y V_x + U_x V_y) = 0$

## So

$p$ ,  $T$ , and  $Rp'$  are coplanar.

$$S = \begin{pmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{pmatrix}$$

$p(S^*R)p' = 0$ . Define  $E = (S^*R)$ . And we have  $pEp' = 0$ .

## The Eight Point Algorithm

- $p^T E p' = 0$ . Each correspondence gives a linear equation in the unknowns of the matrix  $E$ .
- Scale of  $E$  doesn't matter, so it has only 8 unknowns.
- So with 8 correspondences we can determine  $E$  linearly.

## Some subtleties when data isn't perfect

- $E$  has rank 2 (because  $S$  does).
- With noise, we'll get an estimate of  $E$  with full rank. Find best rank 2 approximation.
- Use more points. Write overconstrained system as  $Ae=0$  ( $e$  entries of  $E$  in vector form). Normalize values appropriately. Then SVD of  $A$ . Vector that is closest to its kernel gives entries of  $E$ . Then use SVD to enforce  $E$  has rank 2.

Some practice problems. In all these, there is no rotation, so  $S=E$ .

Suppose  $O = (0,0,0)$  and  $O' = (3,2,4)$ , with a focal length of 1 and no rotation. Then the matrix  $E$  is:

$$\begin{pmatrix} 0 & -4 & 2 \\ 4 & 0 & -3 \\ -2 & 3 & 0 \end{pmatrix}$$

If  $p$  and  $p'$  are corresponding points, show  $p^T E p' = 0$ .

Example: Suppose  $P = (16, 24, 8)$ .  $p = (2,3,1)$ . To find  $p'$  we can translate everything so  $O'$  is the origin and  $P$  would be at  $(13,22,4)$ . Then we'd have  $p' = (3.25, 5.5, 1)$ . Then  $p^T E = (10, -5, -5)$ . And we'd have  $p^T E p' = 32.5 - 27.5 - 5 = 0$ .

If  $p$ ,  $p'$  and  $T$  are coplanar, then if  $p^T E p' = 0$ .

$$E = \begin{pmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{pmatrix}$$

First, let's take an example.

Simplest way for them to be

Coplanar is if all have  $z$  values of 0. So then

$$E = \begin{pmatrix} 0 & 0 & T_y \\ 0 & 0 & T_x \\ -T_y & T_x & 0 \end{pmatrix}$$

Then  $E p' = (0, 0, \text{something})$ , and  $p^T E p' = 0$ .

Suppose  $p_1 = (3,7)$ ,  $p_1'=(1,7)$ ,  $p_2=(5,2)$ ,  $p_2'=(2,2)$ ,  
 $p_3=(6,4)$ ,  $p_3'=(1,4)$ , where  $p_1$  and  $p_1'$  are  
 corresponding points in the first and second images.

What is  $E$ ?

$$p_1 E p_1' = 0 \Rightarrow (3,7,1)(-7T_z + T_y, T_z - T_x, -T_y + 7T_x)^T = 0$$

$$-21T_z + 3T_y + 7T_z - 7T_x - T_y + 7T_x = 0$$

$$2T_y - 14T_z = 0$$

$$p_2 E p_2' = 0 \Rightarrow (5,2,1)(-2T_z + T_y, 2T_z - T_x, -2T_y + 2T_x) = 0$$

$$-10T_z + 5T_y + 4T_z - 2T_x - 2T_y + 2T_x = 0$$

$$3T_y - 6T_z = 0$$

Solving these two equations we get  $T_y=0$ ,  $T_z=0$ .

This means the last equation is:

$$p_3 E p_3' = 0 \Rightarrow (6,4,1)(0, -T_x, 4T_x) = 0$$

$$-4T_x + 4T_x = 0. \text{ So we can't know } T_x.$$

$$E = \begin{bmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{bmatrix}$$

Suppose we have a camera with a focal length of 1  
 and focal point of  $(0,0,0)$ , which translates by  $(1,1,1)$

Suppose  $P_1=(0,0,2)$ ,  $p_1=(0,0,1)$ ,  $p_1'=(-1,-1,1)$ .

$P_2=(2,0,2)$ ,  $p_2=(1,0,1)$ ,  $p_2'=(1,-1,1)$ .

$P_3=(0,2,2)$ ,  $p_3=(0,1,1)$ ,  $p_3'=(1,1,1)$ .

Can we recover the translation using  $p E p' = 0$ ?

$$p_1 E p_1' = 0 \Rightarrow (0,0,1)(T_z + T_y, -T_z - T_x, T_y - T_x) = 0, \quad T_y - T_x = 0$$

$$T_y = T_x$$

$$p_2 E p_2' = 0 \Rightarrow (1,0,1)(T_z + T_y, T_z - T_x, -T_y - T_x) = 0, \quad T_z + T_y - T_y - T_x = 0,$$

$$T_z = T_x.$$

$$p_3 E p_3' = 0 \Rightarrow (0,1,1)(\dots, -T_z - T_x, T_y + T_x) = 0, \quad -T_z + T_y = 0.$$

We get  $T_x = T_y = T_z$ , but we can recover the overall magnitude.

$$E = \begin{bmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{bmatrix}$$
