

# Texture

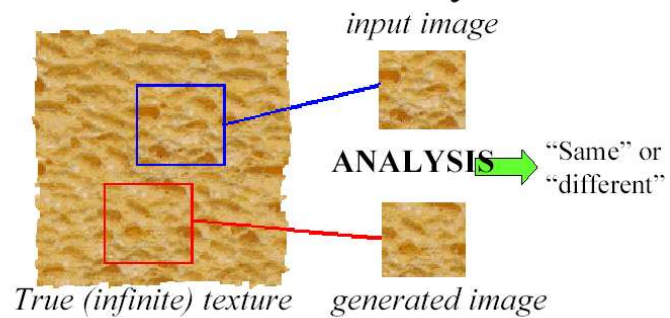

- Edge detectors find differences in overall intensity.
- Average intensity is only simplest difference.

## Issues: 1) Discrimination/Analysis

### The Goal of Texture Analysis

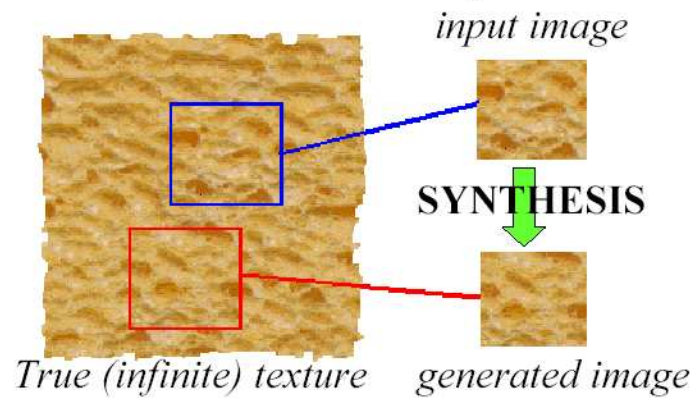

Compare textures and decide if they're made of the same "stuff".

(Freeman)

## 2) Synthesis

### The Goal of Texture Synthesis

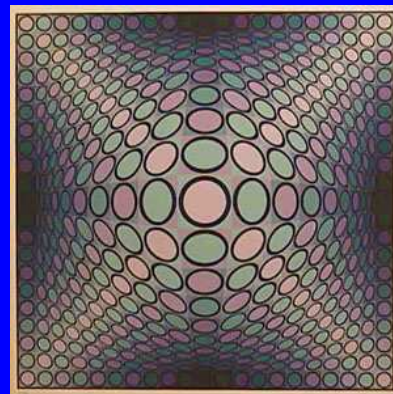

### Many more issues

3. Texture boundary detection.

4. Shape from texture.

We'll focus on 1 and 2.

([www.cmap.polytechnique.fr/~maureen/vasarely3.jpg](http://www.cmap.polytechnique.fr/~maureen/vasarely3.jpg))

## What is texture?

- Something that repeats with variation.
- Must separate what repeats and what stays the same.
- Model as repeated trials of a random process
  - The probability distribution stays the same.
  - But each trial is different.
  - This may be true (eg., pile of objects)
  - Or not really (tile floor).

## Simplest Texture

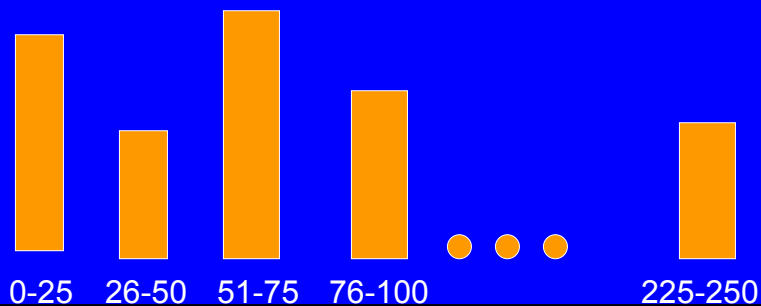

- Each pixel independent, identically distributed (iid).
- Examples:
  - Region of constant intensity.
  - Gaussian noise pattern.
  - Speckled pattern

## Texture Discrimination is then Statistics

- Two sets of samples.
- Do they come from the same random process?

## Simplest Texture Discrimination

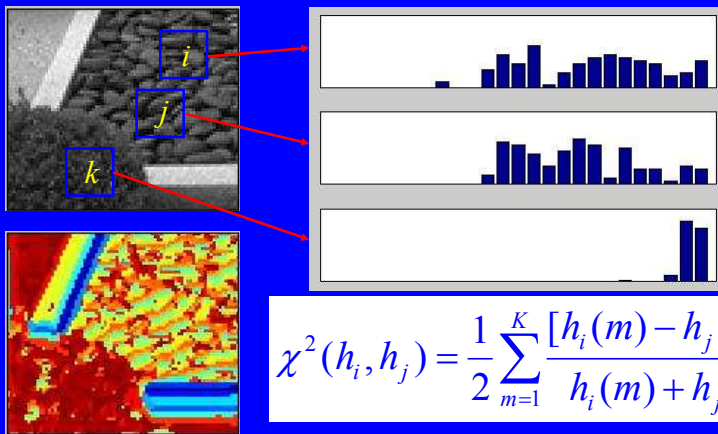

- Compare sample distributions (histograms).
  - Divide intensities into discrete ranges.
  - Count how many pixels in each range.

## How/why to compare

- Simplest comparison is SSD, many others.
- Can view probabilistically.
  - Histogram is a set of samples from a probability distribution.
  - With many samples it approximates distribution.
  - Test probability samples drawn from same distribution. i.e., is difference greater than expected when two samples come from same distribution?

## Chi square distance between texon histograms

(Malik)

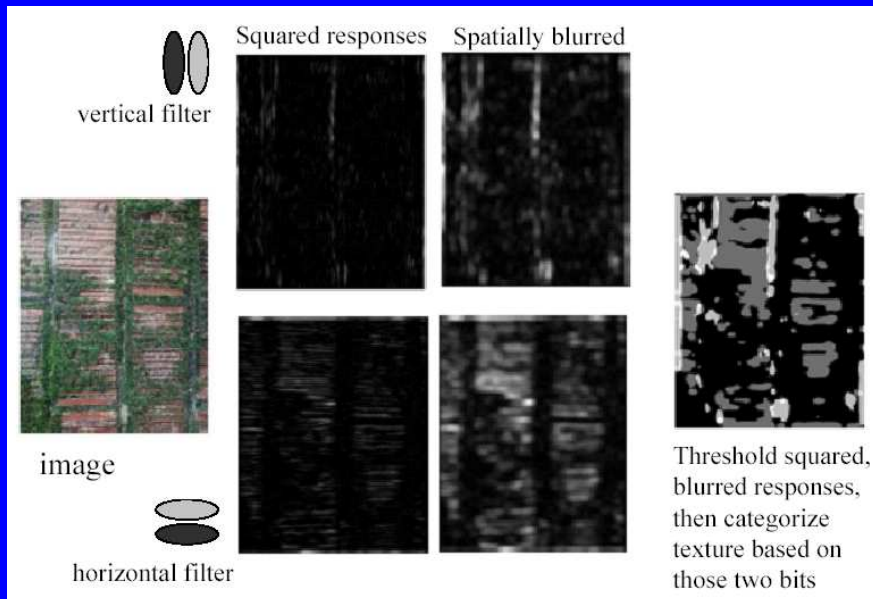

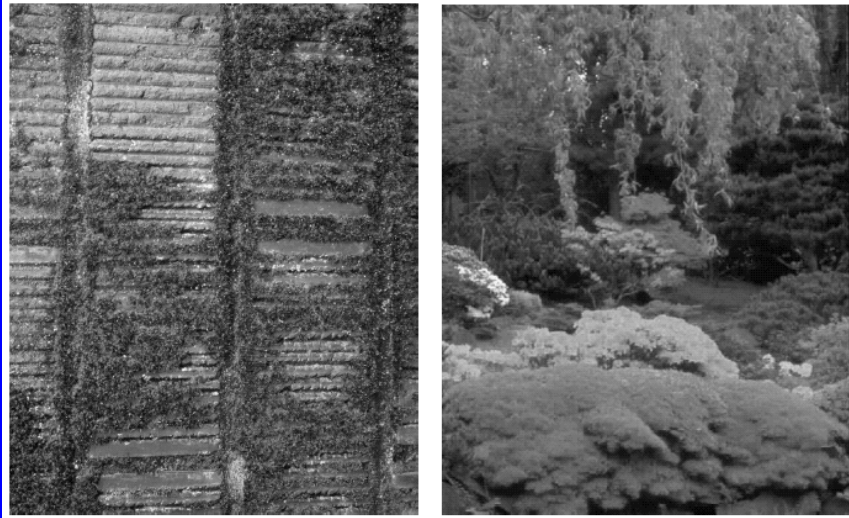

## More Complex Discrimination

- Histogram comparison is very limiting
  - Every pixel is independent.
  - Everything happens at a tiny scale.

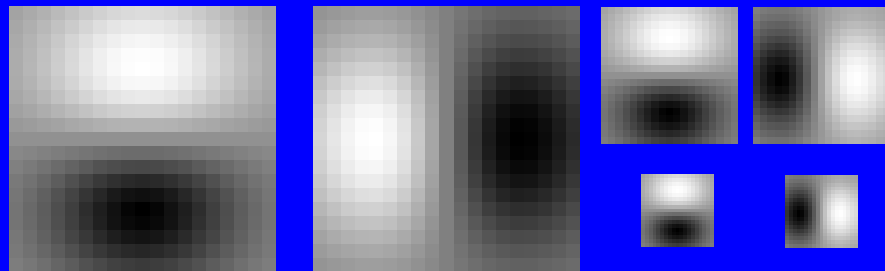

## Wavelet representations

- Wavelet coefficients are less dependent than pixels
  - Neighboring pixels are very dependent.
  - This is why used for compression (JPEG2000).
- Less local, seem to capture more info.

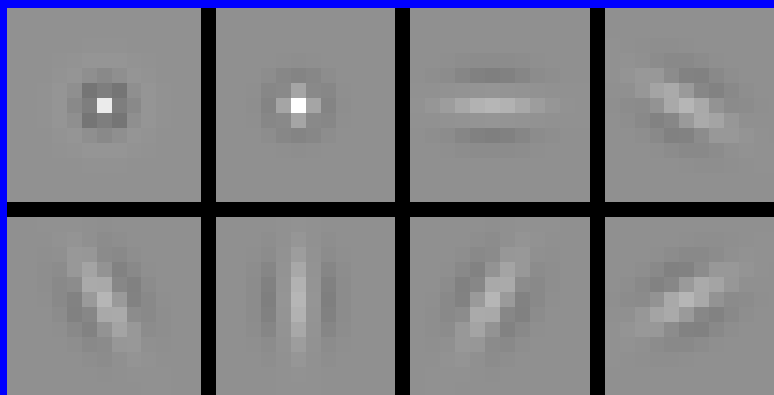

## Example (Forsyth & Ponce)

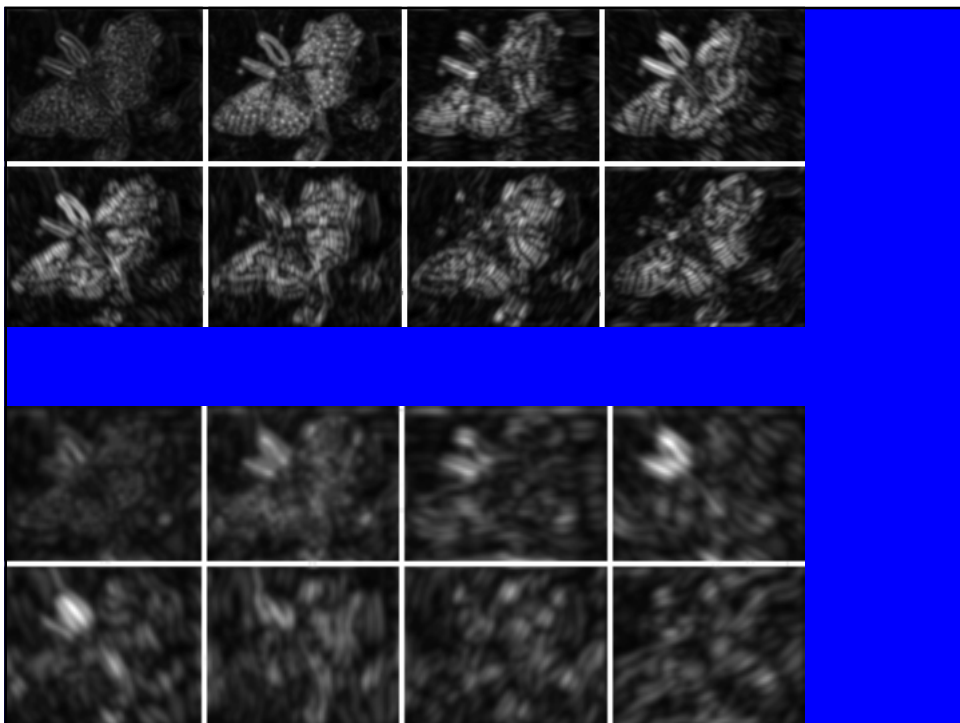

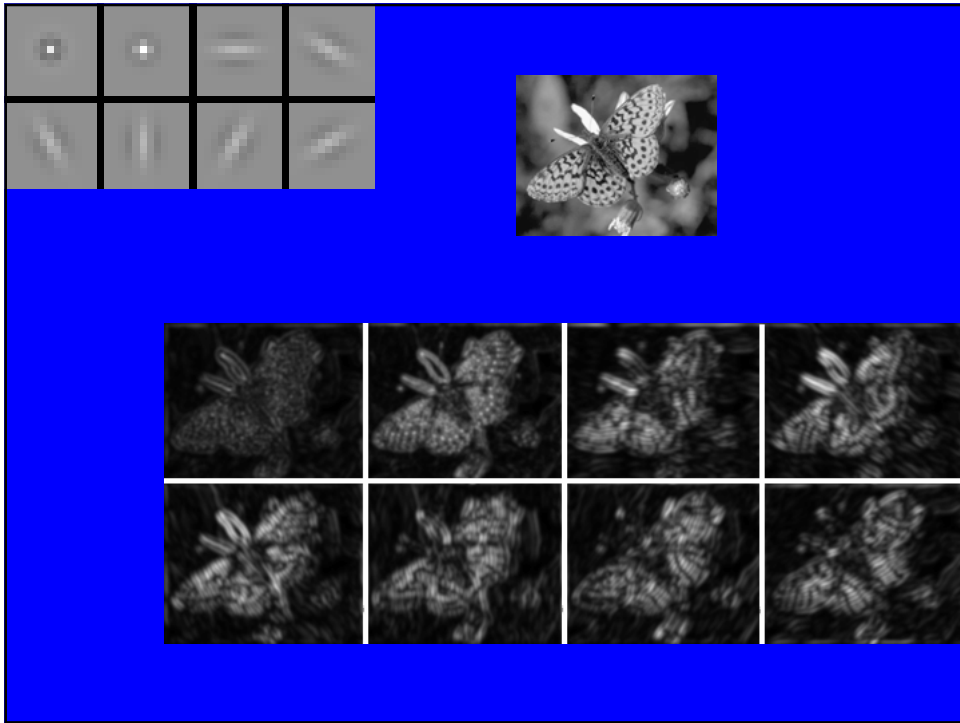

## Difference of Gaussian Filters

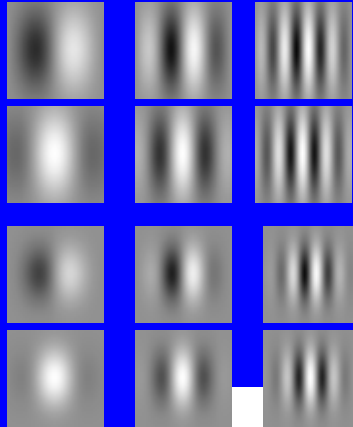

## Spots and Oriented Bars (Malik and Perona)

## Gabor Filters

Gabor filters at different scales and spatial frequencies

top row shows anti-symmetric (or odd) filters, bottom row the symmetric (or even) filters.

$$\cos(k_x x + k_y y) \exp\left\{-\frac{x^2 + y^2}{2\sigma^2}\right\}$$

## Gabor filters are examples of Wavelets

- We know two bases for images:
  - Pixels are localized in space.
  - Fourier are localized in frequency.
- Wavelets are a little of both.
- Good for measuring frequency locally.

## Synthesis with this Representation (Bergen and Heeger)

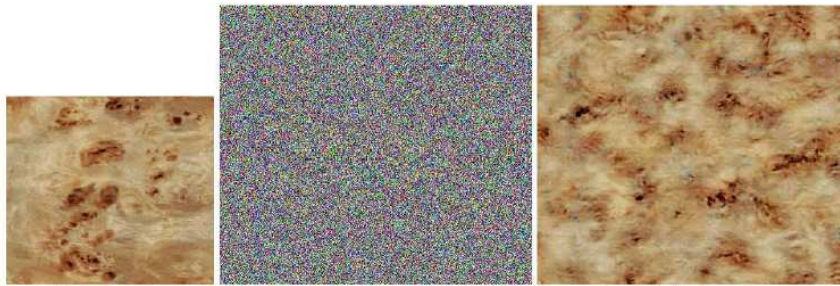

Figure 2: (Left) Input digitized sample texture: burled maple wood. (Middle) Input noise. (Right) Output synthetic texture that matches the appearance of the digitized sample. Note that the synthesized texture is larger than the digitized sample; our approach allows generation of as much texture as desired. In addition, the synthetic textures tile seamlessly.

## Bergen and Heeger results

Figure 3: In each pair left image is original and right image is synthetic: stucco, iridescent ribbon, green marble, panda fur, slag stone, figured yew wood.

## Bergen and Heeger failures

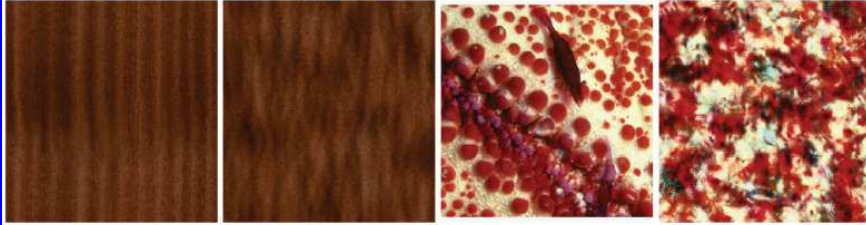

Figure 8: Examples of failures: wood grain and red coral.

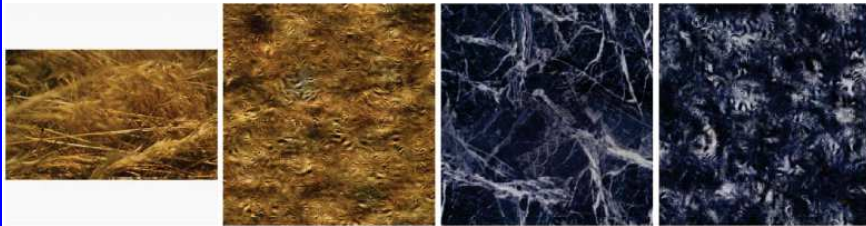

Figure 9: More failures: hay and marble.

## Modeling Dependencies

- Pairwise dependencies
  - Co-occurrence of intensities at different distance/angles.
  - Covariance matrix of pixel and all nearby pixels.

## Gabor vectors

- Compute Gabors at (8) different orientations and (5) scales.
- Each image point -> a point in an 80 dimensional space (each Gabor output is complex).
- Compare histograms in 80D
  - This is hard part.
  - Dividing space into regular buckets doesn't work.
  - Cluster points
    - Assign each point to a cluster
    - Implicitly, this partitions space more intelligently.
  - Compare using Chi-Squared or whatever you like.

## Markov Model

- Captures local dependencies.
  - Each pixel depends on neighborhood.
- Example, 1D first order model

$$\begin{aligned} P(p_1, p_2, \dots, p_n) &= \\ &P(p_1) * P(p_2|p_1) * P(p_3|p_2, p_1) * \dots \\ &= P(p_1) * P(p_2|p_1) * P(p_3|p_2) * P(p_4|p_3) * \dots \end{aligned}$$

## Markov model of Printed English

- From Shannon: “A mathematical theory of communication.”
- Think of text as a 1D texture
- Choose next letter at random, based on previous letters.

FOR THE LETTERS THAT THE TIME OF WHO  
EVER TOLD THE PROBLEM FOR AN  
UNEXPECTED.

## Example 1<sup>st</sup> Order Markov Model

- Each pixel is like neighbor to left + noise with some probability.
- These capture a much wider range of phenomena.

## There are dependencies in Filter Outputs

- Edge
  - Filter responds at one scale, often does at other scales.
  - Filter responds at one orientation, often doesn't at orthogonal orientation.
- Synthesis using wavelets and Markov model for dependencies:
  - DeBonet and Viola
  - Portilla and Simoncelli

## Portilla and Simoncelli

## We can do this without filters

- Each pixel depends on neighbors.
  1. As you synthesize, look at neighbors.
  2. Look for similar neighborhood in sample texture.
  3. Copy pixel from that neighborhood.
  4. Continue.

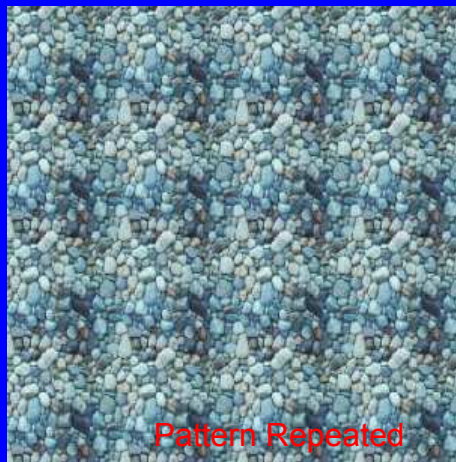

## Efros and Leung

This is like copying, but not just repetition

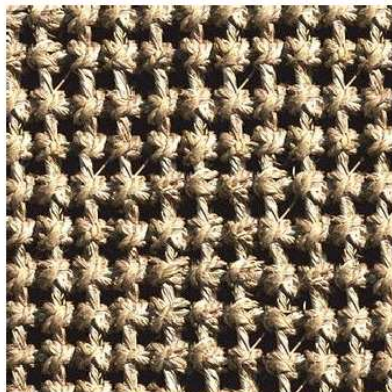

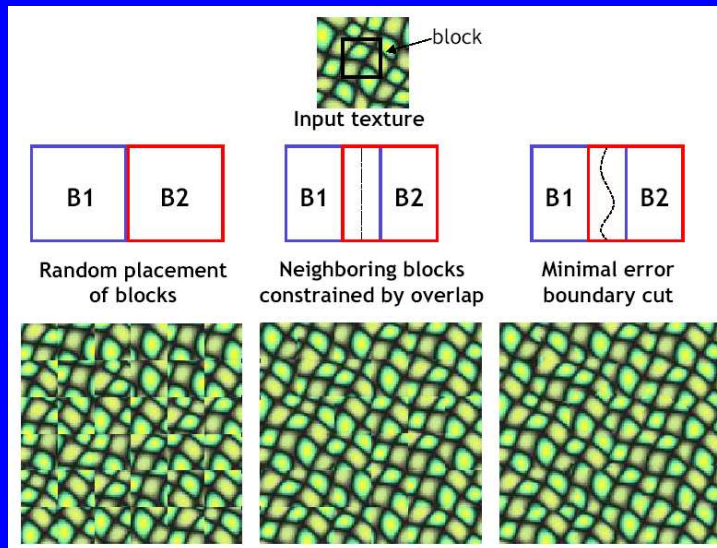

Photo

Pattern Repeated

## With Blocks

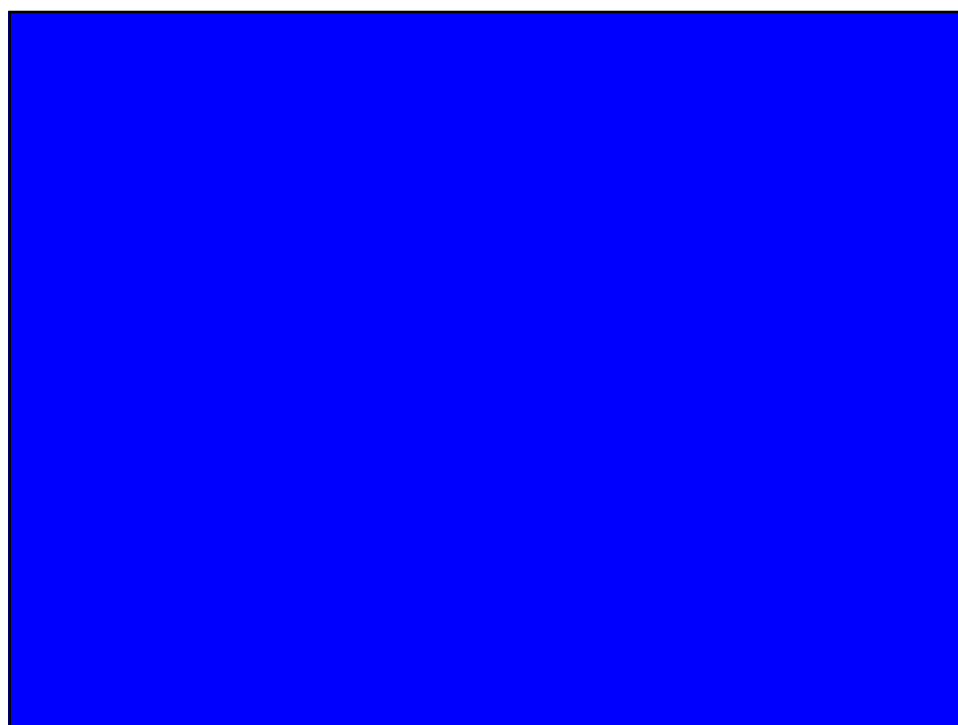

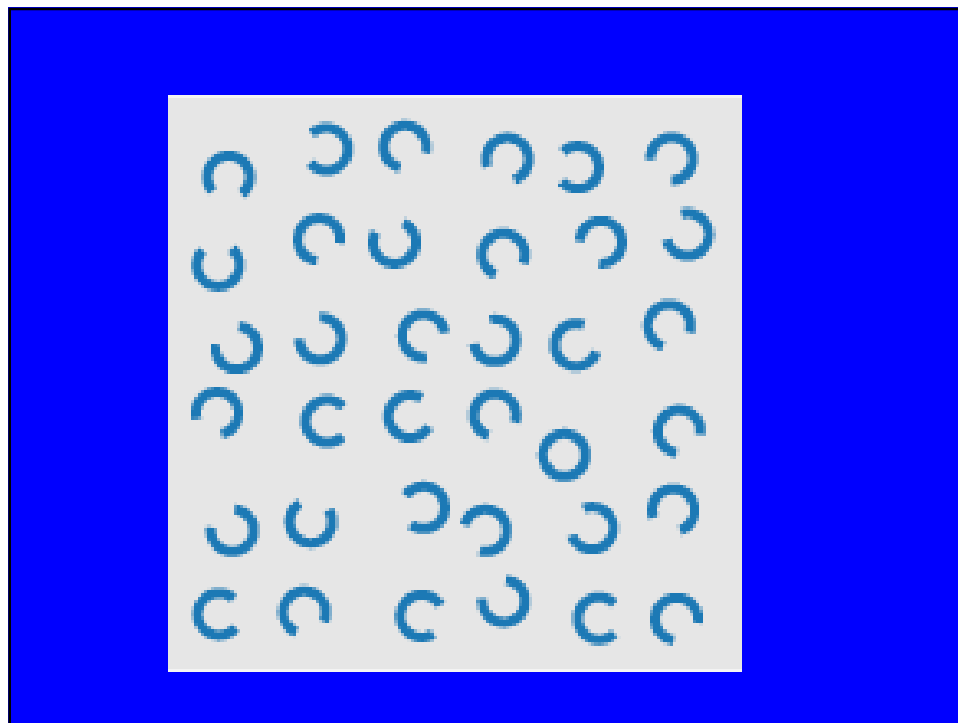

## Conclusions

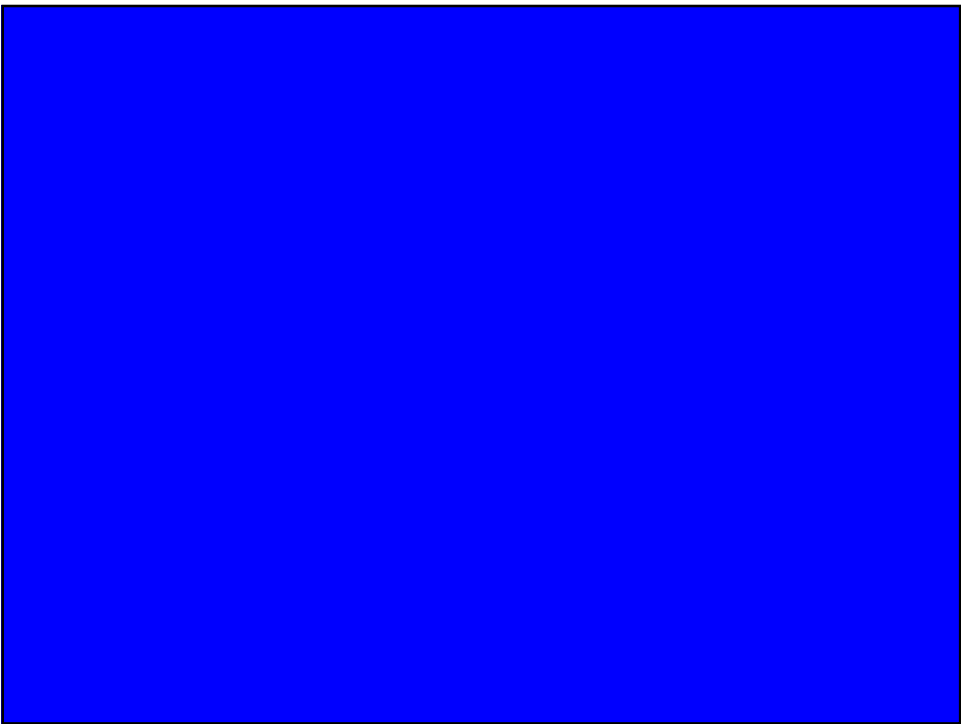

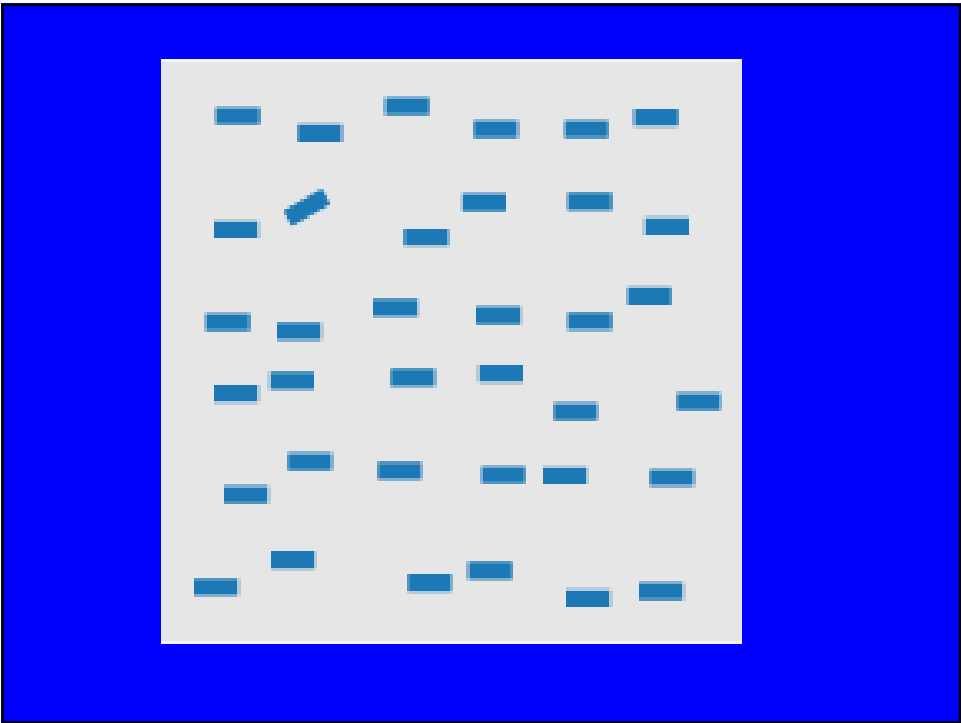

- Model texture as generated from random process.
- Discriminate by seeing whether statistics of two processes seem the same.
- Synthesize by generating image with same statistics.

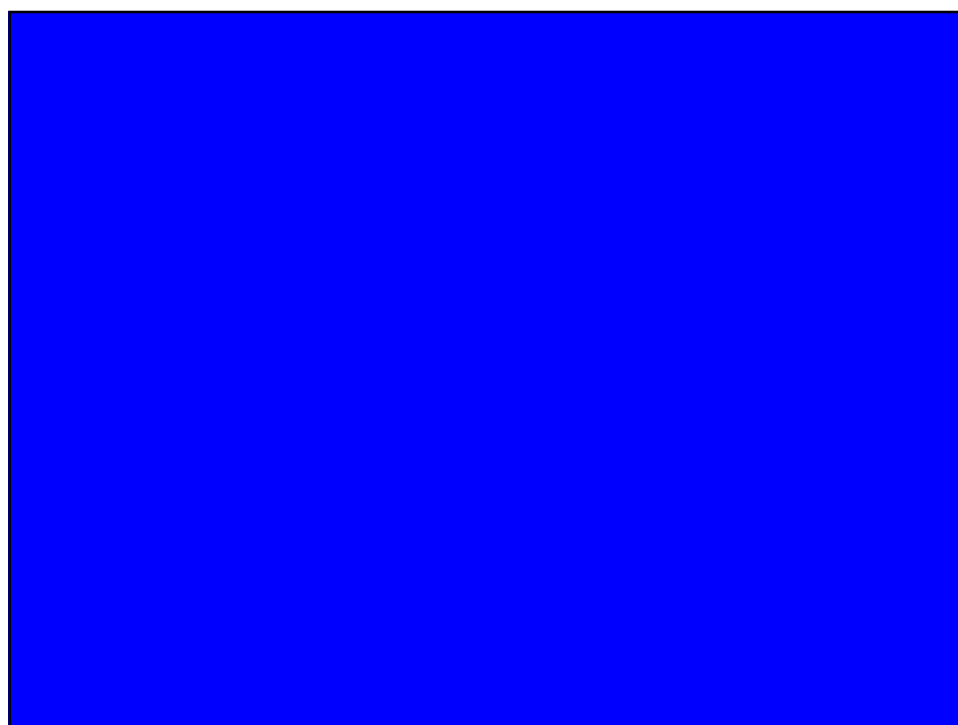

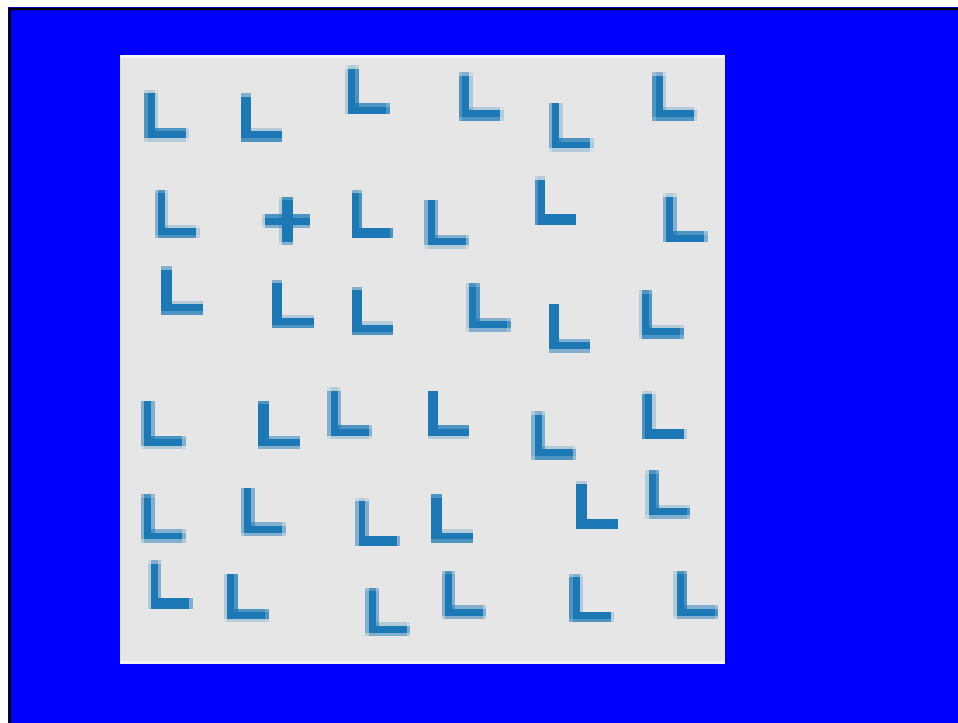

## To Think About

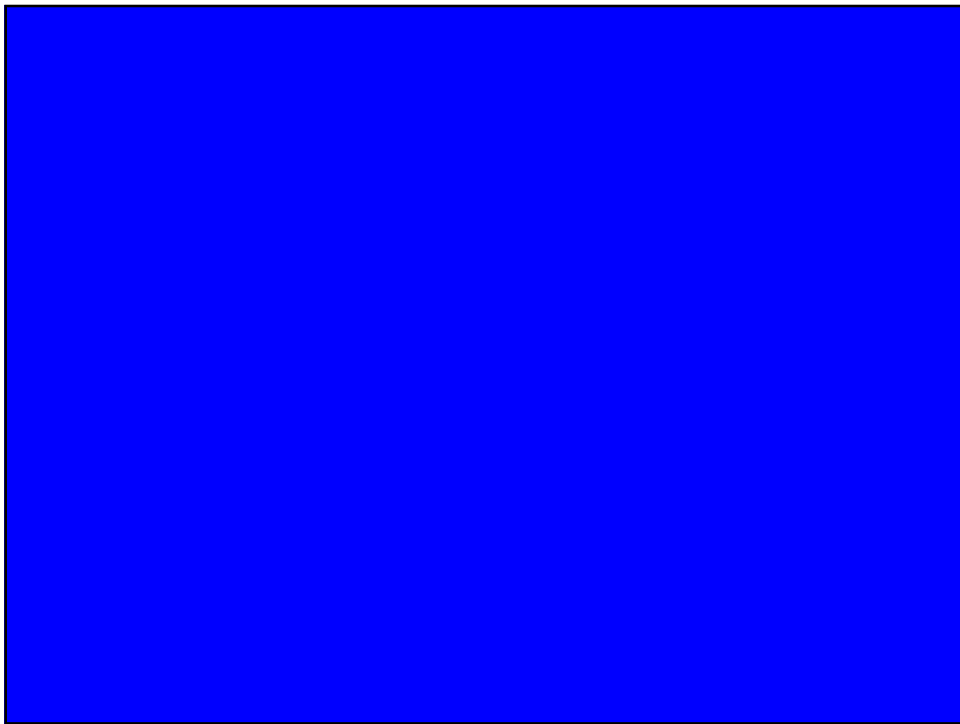

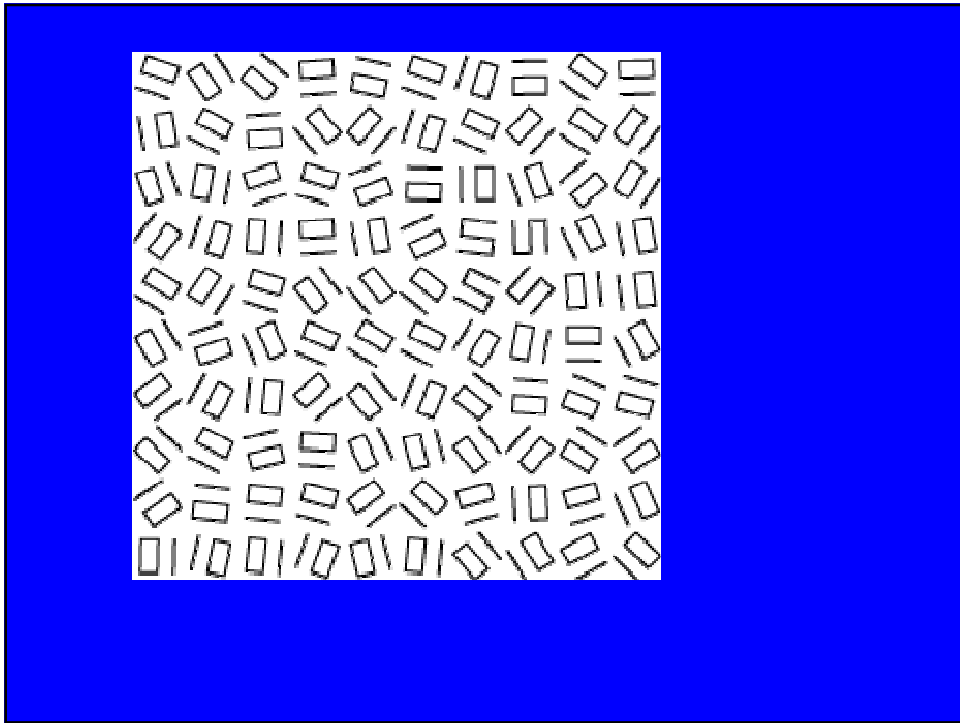

- 3D effects
  - Shape: Tiger's appearance depends on its shape.
  - Lighting: Bark looks different with light angle
- Given pictures of many chairs, can we generate a new chair?
