

Shadows

(Georges de la Tour)

Slide 1

Why Shadows?

- Shadows give us important visual cues about 3D object placement and motion

- Movies are from:

- <http://vision.psych.umn.edu/users/kersten/kersten-lab/demos/shadows.html>

Cast Shadows

Attached Shadows

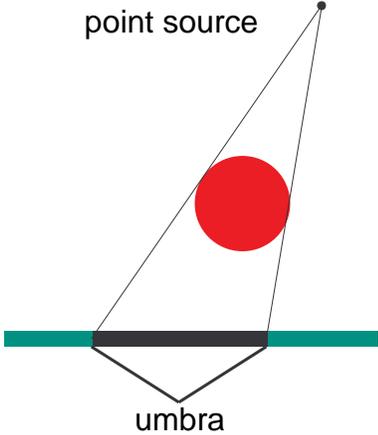

- Attached shadows are easy to render
 - Because they are local.
 - We already have discussed this.
- Cast shadows require us to determine whether the surface is visible to the light.

Real-time Shadows

- Assumptions: hard shadows from point light sources onto planar surfaces
- Let the light source be at infinity in the direction $\mathbf{L}(x_l, y_l, z_l)$, and we want to compute the shadow $S(x_w, y_w, z_w)$ of the point $\mathbf{P}(x_p, y_p, z_p)$, on the plane $z = 0$
- It is easy to see that \mathbf{S} lies on the line defined by \mathbf{P} and \mathbf{L} or
$$\mathbf{S} = \mathbf{P} - \alpha \mathbf{L}$$
- Since the shadow is on the plane $z = 0$,

$$z_w = 0 \Rightarrow \alpha = z_p / z_l, \text{ and}$$

$$x_w = x_p - (z_p / z_l) x_l$$

$$y_w = y_p - (z_p / z_l) y_l$$

Real-time Shadows

Restating the equations from previous slide in a matrix form:

$$\begin{bmatrix} x_w \\ y_w \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & -x_l/z_l & 0 \\ 0 & 1 & -y_l/z_l & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_p \\ y_p \\ z_p \\ 1 \end{bmatrix}$$

Shadows on arbitrary planes can be performed by prefixing the above matrix by a suitable transformation that transforms that plane to $z = 0$

Slide 8

Real-time Shadows

- Remember to set the right shadow color before drawing the shadow
- Z-conflicts can ruin shadows, so remember to slightly offset the shadows to lie above the surface:

```
glEnable(GL_POLYGON_OFFSET_FILL)  
glPolygonOffset(GLfloat factor, GLfloat units)  
// display the polygon here  
glDisable(GL_POLYGON_OFFSET_FILL)
```
- Alternatively if the scene geometry is well understood the following might be possible and simpler:
Render the plane, turn off the depth test, render the shadows, turn the depth test back on, and render the rest of the scene.

Real-time Shadows

We assumed light source at infinity.

If the light source is local at $\mathbf{L}(x_l, y_l, z_l)$, we can use the following matrix [Blinn 88]:

$$\begin{bmatrix} x_w \\ y_w \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} z_l & 0 & -x_l & 0 \\ 0 & z_l & -y_l & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & z_l \end{bmatrix} \begin{bmatrix} x_p \\ y_p \\ z_p \\ 1 \end{bmatrix}$$

Why is this the right matrix? Let's just work through the x coordinate. To project the point onto the $z = 0$ plane as a shadow, we need to move it in the direction from the light to the point, and to move it far enough so that it's on the $z = 0$ plane. That means we need to add a scaled version of $(x_p - x_l, y_p - y_l, z_p - z_l)$ to the point (x_p, y_p, z_p) . Our projected point will be $(x_p, y_p, z_p) + a(x_p - x_l, y_p - y_l, z_p - z_l)$ where we choose a so that the resulting z coordinate will be 0. That is, $z_p + a(z_p - z_l) = 0$, or $a = -z_p / (z_p - z_l)$.

The x coordinate that we wind up with, then will be $x_p + z_p(x_p - x_l) / (z_l - z_p)$. We can rewrite this as:

$$(x_p(z_l - z_p) + z_p(x_p - x_l)) / (z_l - z_p) = (x_p z_l - z_p x_l) / (z_l - z_p).$$

Notice that if we apply our matrix to $(x_p, y_p, z_p, 1)$, we get $(x_p z_l - z_p x_l, ?, 0, z_l - z_p)$, where we haven't calculated the y coordinate yet. This is in homogenous coordinates, but if we divide by the fourth coordinate, we get the correct x coordinate that we have just calculated. We can check the y coordinate in the same way.

Light Maps

- Idea is to store the view-independent lighting of a scene as a 2D texture map
- Light maps are reasonably effective even when used at low resolutions (since they usually don't have high frequency detail)
- Efficiency involves clustering similarly lighted polygonal patches (Zhukov *et al.* 1998)

Shadow Augmented Light Maps

- If light sources and scene objects are static then the shadows will be static.
 - Precompute the shadows as a part of the light map and apply as a texture
- “(The world) saw shadows black until Monet discovered they were coloured,...”

Maugham, Of Human Bondage

Shadow Z-Buffer

- Proposed by Williams 1978
- Render the scene from the light's point of view and store the result in a shadow z-buffer
- Then render the scene from the user's view point and for each pixel that overwrites a previously written pixel:
 - Transform the pixel's screen space coordinates into the light source's coordinate frame
 - Index into the shadow z-buffer to see whether the rendered point's depth is greater than the depth for the corresponding pixel in the shadow z-buffer
 - If the depth is greater \Rightarrow point is in shadow and use the shadow color, otherwise render normally
