## Problem Set 3 Due at *beginning* of class on Mar. 18

1. Basing identification on private-key encryption. Let  $(\mathcal{E}, \mathcal{D})$  be a private-key encryption scheme for k-bit messages, and consider the following identification protocols in the shared-key setting (the prover  $\mathcal{P}$  and verifier  $\mathcal{V}$  begin by sharing a random key  $s \in \{0, 1\}^k$ ):

**Protocol 1.**  $\mathcal{V}$  chooses  $r \in \{0,1\}^k$  at random and sends r to  $\mathcal{P}$ . The prover computes  $C \leftarrow \mathcal{E}_s(r)$  and sends C. The verifier accepts iff  $\mathcal{D}_s(C) \stackrel{?}{=} r$ .

**Protocol 2.**  $\mathcal{V}$  chooses  $r \in \{0,1\}^k$  at random, computes  $C \leftarrow \mathcal{E}_s(r)$ , and sends C to the prover.  $\mathcal{P}$  computes  $r' = \mathcal{D}_s(C)$  and sends r'. The verifier accepts iff  $r \stackrel{?}{=} r'$ .

For each of the following statements, give either a proof of security or a counterexample showing that the statement is, in general, not true. (If you give a counterexample, you need not be completely formal if your counterexample is "obviously" true.)

- If  $(\mathcal{E}, \mathcal{D})$  is secure against ciphertext-only attacks, then Protocol 1 is necessarily secure against weak attacks.
- If  $(\mathcal{E}, \mathcal{D})$  is secure against chosen-plaintext attacks, then Protocol 1 is necessarily secure against passive attacks.
- If  $(\mathcal{E}, \mathcal{D})$  is secure against chosen-plaintext attacks, then Protocol 2 is necessarily secure against passive attacks.
- If  $(\mathcal{E}, \mathcal{D})$  is secure against chosen-plaintext attacks, then Protocol 2 is necessarily secure against active attacks.
