

**1. [20 points]****Part a. [6 points]**

*Inv*  $A_1$  holds, where

$A_1 : \psi(K)$

**Solution**

True.

At the start, only A and B have K; it is not in  $\alpha$ . The only expressions involving K seen by the attacker have the form  $\text{enc}(K, x)$ , where  $x$  is received from the channel. So  $x$  can be a value generated by the attacker, but the attacker cannot set  $x$  to be a simple function of K or to  $\text{dec}(K, K)$ . So  $\text{enc}(K, B.nA)$  does not expose K.

**Part b. [8 points]**

*Inv*  $A_2$  holds, where

$A_2 : ((i \text{ in } \text{hst.keys}) \text{ and } \text{hst}[i] = [B, p]) \Rightarrow ([A, p] \text{ in } \text{hst}[0..i-1])$

**Solution**

False.

Counter-example evolution.

1. Initial step  
After:  $[A, B, 1, 2]$  in chan and in  $\alpha$ ;  $\text{hst} = []$ .
2. Attacker changes msg 1 (i.e., message in step 1) to  $[A, B, 1, 3]$ . (Attacker knows that B's challenge will be 3.)
3. B.1: receive msg 2  
After:  $[B, A, 1, 3, \text{enc}(K, 3)]$  in chan and in  $\alpha$ ; B at 2;  $B.nL = B.nR = 3$ ;  $\text{hst} = []$ .
4. Attacker, using  $\text{enc}(K, 3)$  field in msg 3, sets chan to  $[[A, B, 2, \text{enc}(K, 3)]]$ .
5. B.2: receive msg 4  
After:  $\text{hst} = [[B, \text{enc}(-K, 6)]]$ .  $A_1$  not satisfied.

**Part c. [6 points]**

Attacker cannot learn K by dictionary attack, assuming that K is a weak key.

**Solution**

False

Consider the evolution consisting of the initial step and B.1 (and attacker only eavesdrops).

Then attacker gets:

- 2 //from msg  $[A, B, 1, 2]$  sent in initial step
- $\text{enc}(K, 2)$ ; refer to it as  $z$ . // from B's response msg  $[B, A, 1, 3, \text{enc}(K, 2)]$

Attacker can then do the following off-line dictionary attack:

```
for (cPw in Dictionary) {
    // cPw: candidate password
    cK ← pwToKeyFunction(cPw); // cK: candidate password key
    if (enc(cK, 2) = z)
        cK equals K;
}
```

**2. [10 points]**

Can the attacker obtain data by dictionary attack, assuming  $K$  is a weak key?

**Solution**

Yes.

Here is an evolution ending with the attacker obtaining data.

## 1. Initial step

After: let  $x_A$  be A.nL's value; let  $t_A = A.tL = g^{x_A} \bmod p$ .  $[A,B,1,enc(K,t_A)]$  in  $\alpha$ ;

## 2. Attacker:

remove msg 1; generate random  $x_B$ ;

let  $t_B = g^{x_B} \bmod p$ ; send msg  $[B,A,1,t_B]$ .

## 3. A.1: receive msg 2

After:  $[A,B,2,enc(L,['HELLO',data])]$  in  $\alpha$ , where  $L = t_B^{x_A} \bmod p = g^{x_A \cdot x_B} \bmod p$ .

Attacker now has

- $enc(K,t_A)$ ; let this be  $z1$ . // step 2
- $x_B$ ;  $t_B = g^{x_B} \bmod p$  // step 2
- $enc(L,['HELLO',data])$ ; let this be  $z2$ . // step 3

Attacker can then do the following off-line dictionary attack:

```

for (cPw in Dictionary) {           // cPw: candidate password
  cK ← pwToKeyFunction(cPw);       // cK: candidate password key
  cTA ← dec(cK,z1);                 // cTA: candidate tA
  cKeyDH ← cTAxA mod p;
  cMsg ← dec(cKeyDH, z2);
  if (cMsg.size = 2 and cMsg[0] = 'HELLO')
    data ← cMsg[1];
    // and K = cK and pw = cPw
}

```

---

**3. [20 points]****Part a. [10 points]**

$Inv A_1$  holds, where

$A_1 : \psi(A.Key)$

// attacker does not learn A's current master key

**Solution**

True.

At the start, only A and Z have A.key; attacker does not. `getPwda` does not give the attacker A.key, because it sets A.key to a new value (unknown to attacker) after reading it. Thus the only expressions involving A.key seen by the attacker are sent by Z; they have the form  $enc(A.key, x)$ , where  $x$  involves a random component ( $k_{AB}$ ) and a value received from the channel ( $msg[3]$ ). The attacker can set  $msg[3]$ , but it cannot set  $x$  to a simple function of  $K$  or to  $dec(A.key, A.key)$ . So the attacker cannot compute A.key.

**Part b. [10 points]**

$Inv A_2$  holds, where

$A_2 : ((j \text{ in } hst.keys) \text{ and } j > 0 \text{ and } hst[j] = [B,p]) \Rightarrow hst[j-1] = [A,p]$

**Solution**

False.

Counter-example evolution.

- Attacker eavesdrops an A-B connection, say with session key  $j_{AB}$  and ticket  $jkt$ .  
After this:  $hst = [[A, j_{AB}], [B, j_{AB}]]$ .
- Attacker calls `getPwda` to get A.key's value, i.e.,  $k_{AZ}$ , and set A.key to new value.  
Attacker uses  $k_{AZ}$  to get key  $j_{AB}$  from messages in previous step.
- Attacker connects to B using ticket  $jkt$  and session key  $j_{AB}$ .  
After this:  $hst = [[A, j_{AB}], [B, j_{AB}], [B, j_{AB}]]$ .  $A_2$  does not hold.

In more detail:

1. Initial step  
 $[A,Z,B,.]$  in channel.
2. Z.1: receive msg 1  
 $[Z,A,enc(k_{AZ}, [.,B,j_{AB},jkt])]$  in channel and  $\alpha$ ;  $jkt = enc(k_{BZ}, [j_{AB},A])$ .
3. A.1: receive msg 2; send msg  $[A,B,1,jkt,enc(j_{AB},.)]$ .
4. B.1: receive msg 3; send msg  $[B,A,enc(j_{AB},.)]$ .
5. A.2: receive msg 4; send msg  $[A,B,enc(j_{AB},.)]$ ; update  $hst$  to  $[[A,j_{AB}]]$ ; send msg  $[A,Z,B,.]$ .
6. B.2: receive msg 5; update  $hst$  to  $[[A,j_{AB}], [B,j_{AB}]]$ .
7. Attacker: call `getPwda` to get  $Tk_{AZ}$ ; decrypt field 2 of msg 2 using  $Tk_{AZ}$  to get  $j_{AB}$ ; send msg 3.
8. B.1: receive msg 7; send msg  $[B,A,enc(k_{AB}, [.,y_B])]$ , where  $y_B = B.nL$ .
9. Attacker: receive msg 8; send msg  $[A,B,enc(j_{AB},y_B-1)]$ .
6. B.2: receive msg 9; update  $hst$  to  $[[A,j_{AB}], [B,j_{AB}], [B,j_{AB}]]$ .  
At this point,  $A_2$  does not hold.
