

CMSC433, Fall 2001 Programming Language Technology and Paradigms

Alan Sussman
September 4, 2001

Administrivia

- Quiz answers posted on Exams web page
- C++ readings from textbook posted on Readings web page
 - supplements material in lectures
- C++ lecture notes will be posted on Lectures web page regularly

CMSC 433, Fall 2001 - Alan Sussman

2

Administrivia (cont.)

- Class account info emailed Friday
 - if you didn't get it, see me after class or in office hours
- My office hours will be posted on class home page
 - TA's coming soon too
- Project 1 - C++ - due Thursday, Sept. 20

CMSC 433, Fall 2001 - Alan Sussman

3

Project 1

- C++ Linked List and Expanding Int Array
 - don't use other C++ libraries
 - Expanding Int array should use shared representation, copy on write
 - so that copying is fast
- Specification posted today on web page under Projects link
 - more discussion Thursday

CMSC 433, Fall 2001 - Alan Sussman

4

Quiz answers

Copy constructor

```
SimpleArray(const SimpleArray & that) {  
    length = that.length;  
    data = new int[length];  
    for(int i = 0; i < length; i++)  
        data[i] = that.data[i];  
}
```

CMSC 433, Fall 2001 - Alan Sussman

6

BAD Copy constructor

```
// DO NOT DO THIS
SimpleArray(const SimpleArray & that) {
    *this = that;
}
```

CMSC 433, Fall 2001 - Alan Sussman

7

Operator=

```
SimpleArray& operator=(const SimpleArray & that)
{
    if (this == &that) return *this;
    delete [] data;
    length = that.length;
    data = new int[length];
    for(int i = 0; i < length; i++)
        data[i] = that.data[i];
    return *this;
}
```

CMSC 433, Fall 2001 - Alan Sussman

8

operator= notes

- operator= is not operator==
- generally better to define as member function than standalone
- check for this == &that
- free storage for this

CMSC 433, Fall 2001 - Alan Sussman

9

Destructor

```
~SimpleArray() {
    delete [] data;
}
```

CMSC 433, Fall 2001 - Alan Sussman

10

destructor notes

- no need to set length = 0 or data = null
- Everything is much simpler if you never allow data==null

CMSC 433, Fall 2001 - Alan Sussman

11

implementing OnePlaceBuffer

```
public class Buf implements cmsc433.OnePlaceBuffer {
    private Object data;
    public synchronized Object take()
        throws InterruptedException {
        while (data == null)
            wait();
        Object tmp = data;
        data = null;
        notifyAll();
        return tmp;
    }
}
```

CMSC 433, Fall 2001 - Alan Sussman

12

OnePlaceBuffer (cont.)

```
public synchronized void put(Object o)
    throws InterruptedException {
    while (data != null)
        wait();
    data = o;
    notifyAll();
}
```

CMSC 433, Fall 2001 - Alan Sussman

13

C++

C++ without Classes

- Don't need to say "struct"
- New libraries
- function overloading
 - confusing link messages
- default parameters
- **void ***
 - C++ requires explicit conversion from **void ***

CMSC 433, Fall 2001 - Alan Sussman

15

More C++ without Classes

- Dynamic initialization of globals
 - no way to control order between files
- References
 - Compiler treats as pointers
 - Programmer doesn't
 - Once initialized to reference an address, cannot be made to reference a different address
 - Used for pass-by-reference parameters

CMSC 433, Fall 2001 - Alan Sussman

16

References

```
int x,y;
int *p = &x;
int &q = y;
q++; // increments y
(*p)++; // increments x
q = x; // assigns value of x to y
p=&y; // makes p point to y;
```

CMSC 433, Fall 2001 - Alan Sussman

17

new/delete

- use **new A** to allocate one A
- use **new A[size]** to allocate an array of **size** A's
- use **delete** to free one A
- use **delete[]** to free an array of A
- invokes constructors and destructors
 - for all elements of an array
 - **delete[]** must be given pointer to first element

CMSC 433, Fall 2001 - Alan Sussman

18

Data Abstraction

- Avoid name clashes
- Hide implementation
- Override “standard” functionality

CMSC 433, Fall 2001 - Alan Sussman

19

IntArray example

- Without OO:

```
void IA_init(IntArray *ia);
void IA_cleanup(IntArray *ia);
void IA_setSize(IntArray *ia, int value);
int IA_getSize(IntArray *ia);
void IA_setElem(IntArray *ia,
                int index, int value);
int IA_getElem(IntArray *ia, int index);
```

- With OO:

```
class IntArray{
public:
    IntArray();
    ~IntArray();
    void setSize(int value);
    int getSize();
    void setElem(int index,
                int value);
    int getElem(int index);
private:
    ...}
```

CMSC 433, Fall 2001 - Alan Sussman

20

Access control

- A member can be public/protected/private
- An access specification controls access to all following members (until the next access specification)
- For classes, initial/default access is private
 - For structs, initial/default access is public
 - no other difference between classes and structs

CMSC 433, Fall 2001 - Alan Sussman

21

Access levels

- public – any function/method allowed access
- private - only methods in the class allowed access
- protected - like private, except that subclasses (derived classes) can access inherited members

CMSC 433, Fall 2001 - Alan Sussman

22

Protected access

- Class A {
 private: int x;
 protected: int y; }
- Class B : public A {
 static int foo(A a, B b) {
 int i = a.x; // illegal
 int j = a.y; // illegal
 int k = b.x; // illegal
 int n = b.y; // LEGAL
 ...}

CMSC 433, Fall 2001 - Alan Sussman

23

Friends

- A class X can declare a class Y or a function f as a friend
 - Gives Y or f access to all of X's private and protected data
- Friendship is not transitive
 - If X declares Y as a friend, and Y declares Z as a friend, Z can't see X's private data
- It's not inherited either
 - a class derived from Y cannot access X's private or protected data

CMSC 433, Fall 2001 - Alan Sussman

24

Hidden functions

- class A {
 A(); // void (or default) constructor
 A(const A &); // copy constructor
 A& operator=(const A &) // operator=
 ~A(); // destructor
}

CMSC 433, Fall 2001 - Alan Sussman

25

void/default constructor

- Invoked whenever an instance is created without being initialized.
- If no constructor is provided, default public one is created by compiler
 - invokes void constructor on each base class and instance variable (member)
 - members of built-in types not initialized

CMSC 433, Fall 2001 - Alan Sussman

26

copy constructor

- Invoked to create a new value from an old value
 - for initialization
 - for parameters passed by value
 - for objects returned as values
- If no copy constructor supplied, default public one created by compiler
 - invokes copy constructor for each base class and instance variable (and copies bits for built-in types)
 - almost never correct if you have pointers
- If copy constructor supplied, must also supply void constructor

CMSC 433, Fall 2001 - Alan Sussman

27

CMSC433, Fall 2001 Programming Language Technology and Paradigms More C++

Alan Sussman
September 6, 2001

Administrivia

- Office hours – Tu 3:30-4:30, Wed 11-noon
 - and by appointment
 - subject to change
 - still no TA
- Project 1

CMSC 433, Fall 2001 - Alan Sussman

29

Project 1

- Issues
 - reusing IntList cells for operator=
 - IntListf::pop() and push() are to front of list (like a stack)
 - IntList::appendCopyAtEnd() appends to end of list
 - be careful appending an IntList to itself
 - ElementRef for IntEArray
 - don't create objects of type ElementRef explicitly
 - ElementRef really should be an *inner class* of IntEArray

CMSC 433, Fall 2001 - Alan Sussman

30

Last time

- C++ without classes
 - function overloading
 - default parameters
 - dynamic global initialization
 - references
 - new/delete
- Classes
 - data abstraction
 - access control – public, private, protected, friend
 - hidden functions – void constructor, copy constructor

CMSC 433, Fall 2001 - Alan Sussman

31

operator=

- If no operator=() defined, compiler defines default public one
 - does operator= on each base class and instance variable
- Watch for a = a
- A::operator=(const A&) usually returns A&
 - allows a = b = c;

CMSC 433, Fall 2001 - Alan Sussman

32

Pointer obligations

- For the hidden functions, if you have a member variable that is a pointer, the default functions are almost certainly wrong
- For each pointer, decide if it is the unique pointer to an object
 - if not, need to control updates of that object and figure out when to free referenced object
 - if so, need to duplicate object rather than pointer

CMSC 433, Fall 2001 - Alan Sussman

33

Pointer obligations, with concise syntax

```
class IntArray {
    int *rep;
    int size;
public:
    IntArray(int sz) : rep(new int[sz]), size(sz) {};
    IntArray(const IntArray &a)
        : rep(new int[a.size]), size(a.size)
        { memcpy(rep, a.rep, sizeof(int)*a.size); }
    ~IntArray() {
        delete [] rep;
    }
}
```

CMSC 433, Fall 2001 - Alan Sussman

34

operator =

```
IntArray& operator=(const IntArray &a) {
    if (this == &a) return *this;
    if (size != a.size) {
        delete [] rep;
        rep = new int[a.size];
        size = a.size;
    }
    memcpy(rep, a.rep, sizeof(int)*size);
    return *this;
}
```

CMSC 433, Fall 2001 - Alan Sussman

35

One arg constructors

- A one argument constructor is also used for type conversion
 - A(int sz) allows an int to be used anywhere an A is expected
 - only one level of conversion is supported
 - if a B is required and an int is supplied, the system won't convert an int to an A, which is then converted to a B
 - Can mark constructor as **explicit** to avoid this feature

CMSC 433, Fall 2001 - Alan Sussman

36

Subtyping – Derived classes

- if class D has class B as a public base type
 - a pointer to a D can be provided anywhere a pointer to a B is expected
 - a reference to a D can be provided anywhere a reference to a B is expected
- class D should fulfill B's public contract
 - something that expects a pointer to a B
 - and is given a pointer to a D
 - shouldn't be surprised

CMSC 433, Fall 2001 - Alan Sussman

37

Virtual functions

- Without virtual functions, B's functionality will be invoked on objects *pointed to* by a B *pointer*
 - determined from explicit type of pointer
- With virtual functions
 - dispatching based on run-time type of object pointed to
 - and compile-time type of arguments
 - must match argument types exactly to override in derived class

CMSC 433, Fall 2001 - Alan Sussman

38

Non-virtual functions

- non-virtual functions have confusing semantics
 - function you get depends on type of pointer used to reference the object
- but virtual functions may be more expensive to invoke
- should probably make functions non-virtual only if never overridden
 - final in Java

CMSC 433, Fall 2001 - Alan Sussman

39

Common Subtyping Errors

- An array of D's can be given to someone
 - who expects an array of B's
- B's public contract may involve assigning another B to it
- What is the right thing to do
 - when a D is assigned a B?
 - when a B is assigned a D?

CMSC 433, Fall 2001 - Alan Sussman

40

Operator= and subtyping

- struct B {
 B& virtual operator=(const B & b) {...} };
- struct D : public B {
 D & virtual operator=(const D & d) {...} };
- B b; D d; B* pbb = &b; B* pbd = &d;
 - b = d; // B::operator=(const B&)
 - d = b; // Illegal (why?)
 - *pbb = *pbd; // B::operator=(const B&)
 - *pbd = *pbb; // B::operator=(const B&)

CMSC 433, Fall 2001 - Alan Sussman

41

Virtual operator=

- virtual declaration didn't matter; arguments not identical
 - struct B {
 B& virtual operator=(const B & b) {...} };
 - struct D : public B {
 D & virtual operator=(const B & b) {...};
 D & virtual operator=(const D & d) {...};

CMSC 433, Fall 2001 - Alan Sussman

42

Similar problems elsewhere

- Copy constructor
 - overriding not an issue
 - watch out for omitting & for a reference parameter
- operator==
 - almost identical set of problems to operator=

CMSC 433, Fall 2001 - Alan Sussman

43

Covariance of return types

- When you override a function, your return type can be a subtype of the method you are overriding
 - struct B {
 virtual B* getChild();
}
 - struct D : public B {
 virtual D* getChild();
}

CMSC 433, Fall 2001 - Alan Sussman

44

Covariance

- Covariance of return types is OK
 - Somebody who expects a B*, is given a D*
 - invokes getChild() on it
 - Expects a B*, is given a D*
 - No surprise...
- Not OK for argument types
- Co-variance = (in the same way)(vary)
 - as opposed to contravariance
 - allowed in some OO languages for arguments, but not that useful

CMSC 433, Fall 2001 - Alan Sussman

45

Argument types can't be covariant

- Consider if D::f overrode B::f in
 - struct B {virtual void f(B* p);}
 - struct D : public B {virtual void f(D* p);}
- Somebody who expects a B*, is given a D*
 - invokes f(new B()) on it
 - D::f would be surprised!
 - expected a D*, got a B*

CMSC 433, Fall 2001 - Alan Sussman

46

Function hiding

- In class B, if you define f(int)
- In derived class D, you define f(char *)
- f(int) can't be invoked on objects of type D
- except though a B* pointer
- violates contractual obligation
- Why?
 - Hides operator= ?
 - prevents surprises

CMSC 433, Fall 2001 - Alan Sussman

47

Object Hierarchy Design

- composition/aggregation
 - have components as instance variables
- derivation
 - have components as base classes

CMSC 433, Fall 2001 - Alan Sussman

48

Engine vs. Car

- Should a Car have an Engine as a component or as a base type?

CMSC 433, Fall 2001 - Alan Sussman

49

Animal class

- Say we have classes for Fish, Dog, Eagle, Whale and Hippo.
- Should they have a common base class?
- What methods should it support?
 - age()?
 - speed()?
 - fly()?
 - eat()?

CMSC 433, Fall 2001 - Alan Sussman

50

Heterogeneous collections

- Will you ever need a collection that contains objects that all is-a/has-a/are-a **A**
 - If so, use is-a (derivation)
- Will you need a collection of engines and cars?
- Will you need a collection of animals?

CMSC 433, Fall 2001 - Alan Sussman

51
