

CMSC 106

Lecture Set #4

Set Started:
Friday, September 16, 2011

- **Function definition**
 - Gives a name to a group of statements which can then be executed (called) just using that name.
- **Mathematical functions**

$$\sin(x) = y$$

^ ^ ^
+-- argument

function's result

+-- function name
- In C, function result is called return value.

Defining a function

- **Functions must be defined to be used.**
- Definition gives
 - **type of its return value**
 - **function's name** (same rules as variable names)
 - **names and types of its parameters**
 - its **statements** (or body)

```
ftype fname(parameterlist)
{
    body of function
}
```

- **If type omitted** an int type is assumed.
- **If no return type is desired** the term **void** should be used.
- **If parameter list is empty** the term **void** should be used.
- **The body** should have a **return** statement where the type matches the return type specified.
- **The fname** must be unique.
- **A function can NOT be defined inside another one.**

Simple example function definition:

```
void error_msg(void) {
    printf("This ");
    printf("is Bad Input\n");
    return;
}
```

- function **name** = "error_msg"
- **return type** = nothing
- **list of parameters** = empty
- **body** has only three statements

Calling (executing) a function:

- general form:
 - **function-name(any arguments)**
- as a statement:
 - **printf("Hello,");**
- or as an expression in assignment:
 - **ch = scanf("%d%d%d",&a,&b,&c);**

Examples

- parameter passing example
- return value example
- function calling function example
