CMSC 330: Organization of Programming Languages

Functional Programming with Lists

Lists in OCaml

- The basic data structure in OCaml
 - Lists can be of arbitrary length
 - Implemented as a linked data structure
 - Lists must be homogeneous
 - All elements have the same type
- Operations
 - Construct lists
 - Destruct them via pattern matching

Constructing Lists: Syntax

Syntax

- [] is the empty list (pronounced "nil")
- e1::e2 prepends element e1 to list e2
 - Operator :: is pronounced "cons"
 - e1 is the head, e2 is the tail
- [e1;e2;...;en] is syntactic sugar for e1::e2::...::en::[]

Examples

```
3::[] (* The list [3] *)
2::(3::[]) (* The list [2; 3] *)
[1; 2; 3] (* The list 1::(2::(3::[])) *)
```

Both *cons* and *nil* are terms from LISP

[1,2,3] is **not** a **list**! [1;2;3] is.
Using the former may lead to

confusing error

messages.

Beware:

Constructing Lists: Evaluation

Evaluation

- [] is a value
- To evaluate [e1; ...; en]
 - evaluate e1 to a value v1,
 - **–** ...,
 - evaluate en to a value vn,
 - and return [v1;...; vn]
- Desugaring: evaluate e1::e2
 - evaluate e1 to a value v1,
 - evaluate e2 to a (list) value v2,
 - and return v1:: v2

Remember: Evaluation order in OCaml is right to left (not left to right);

Constructing Lists: Examples

```
# let y = [1; 1+1; 1+1+1] ;;
val y : int list = [1; 2; 3]
# let x = 4::y ;;
val x : int list = [4; 1; 2; 3]
# let z = 5::y ;;
val z : int list = [5; 1; 2; 3]
# let m = "hello"::"bob"::[];;
val m : string list = ["hello"; "bob"]
```

Constructing Lists: Typing

```
Polymorphic type:
<u>Nil:</u>
                                          like a generic type in Java
[]: ('a list
i.e., empty list has type t list for any type t
Cons:
If e1: t and e2: t list then e1::e2: t list
With parens for clarity:
If e1: t and e2: (t list) then (e1::e2): (t list)
```

Examples

```
# let x = [1;"world"] ;;
This expression has type string but an expression was
 expected of type int
# let m = [[1];[2;3]];;
val y : int list list = [[1]; [2; 3]]
\# let y = 0::[1;2;3] ;;
val y : int list = [0; 1; 2; 3]
# let w = [1;2]::y ;;
This expression has type int list but is here used with
  type int list list
```

- The left argument of :: is an element, the right is a list
- Can you construct a list y such that [1;2]::y makes sense?

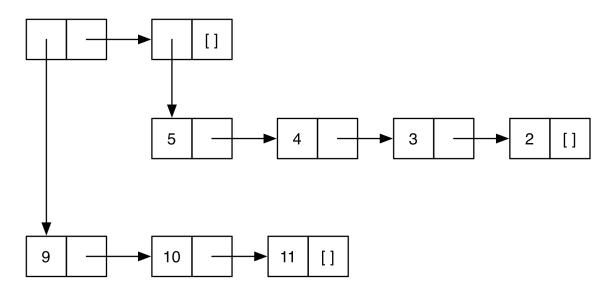

Lists in Ocaml are Linked

- [1;2;3] is represented as shown above
 - A nonempty list is a pair (element, rest of list)
 - The element is the head of the list
 - The pointer is the tail or rest of the list
 - ...which is itself a list!
- Thus in math (i.e., inductively) a list is either
 - The empty list []
 - Or a pair consisting of an element and a list
 - This recursive structure will come in handy shortly

Lists of Lists

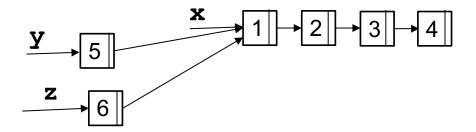

- Lists can be nested arbitrarily
 - Example: [[9; 10; 11]; [5; 4; 3; 2]]
 - Type int list list, also written as (int list) list

Lists are Immutable

- No way to mutate (change) an element of a list
- Instead, build up new lists out of old, e.g., using ::

```
let x = [1;2;3;4]
let y = 5::x
let z = 6::x
```

What is the type of the following expression?

```
[1.0; 2.0; 3.0; 4.0]
```

- A. array
- B. list
- C. float list
- D. int list

What is the type of the following expression?

```
[1.0; 2.0; 3.0; 4.0]
```

- A. array
- B. list
- C. float list
- D. int list

What is the type of the following expression?

```
10::[20]
```

- A. int
- B. int list list
- C. int list
- D. error

What is the type of the following expression?

```
10::[20]
```

- A. int
- B. int list list
- C. int list
- D. error

What is the type of the following definition?

```
let f x = "alien"::[x]
```

- A. string -> string
- B. string list
- C. string list -> string list
- D. string -> string list

What is the type of the following definition?

```
let f x = "alien"::[x]
```

- A. string -> string
- B. string list
- C. string list -> string list
- D. string -> string list

Pattern Matching

- To pull lists apart, use the match construct
- Syntax

```
match e with
/ p1 -> e1
| ...
| pn -> en
```

- p1...pn are patterns made up of [], ::, constants, and pattern variables (which are normal OCaml variables)
- e1...en are branch expressions in which pattern variables in the corresponding pattern are bound

Pattern Matching: Evaluation

- To pull lists apart, use the match construct
- Syntax

```
match e with
/ p1 -> e1
| ...
| pn -> en
```

- Evaluate e to a value v
- If p1 matches v, eval e1 to v1 and return it

...

- Else if pn matches v, evaluate en to vn and return it
- Else, no patterns match: raise Match failure exception

When evaluating branch expression *ei*, any **pattern variables in** *pi* are bound in *ei*, i.e., they are in scope

Pattern Matching Example

```
let is_empty l =
  match l with
  [] -> true
  | (h::t) -> false
```

Example runs

```
is_empty [] (* evaluates to true *)
is_empty [1] (* evaluates to false *)
is empty [1;2] (* evaluates to false *)
```

Pattern Matching Example (cont.)

```
let hd l =
  match l with
  (h::t) -> h
```

Example runs

```
- hd [1;2;3] (* evaluates to 1 *)
- hd [2;3] (* evaluates to 2 *)
- hd [3] (* evaluates to 3 *)
- hd [] (* Exception: Match failure *)
```

To what does the following expression evaluate?

```
match [1;2;3] with [] -> [0] | h::t -> t
```

```
A. []
B. [0]
C. [1]
D. [2;3]
```

To what does the following expression evaluate?

```
match [1;2;3] with [] -> [0] | h::t -> t
```

```
A. []
B. [0]
C. [1]
D. [2;3]
```

"Deep" pattern matching

- You can nest patterns for more precise matches
 - a::b matches lists with at least one element
 - Matches [1;2;3], binding a to 1 and b to [2;3]
 - a::[] matches lists with exactly one element
 - Matches [1], binding a to 1
 - Could also write pattern a::[] as [a]
 - a::b::[] matches lists with exactly two elements
 - Matches [1;2], binding a to 1 and b to 2
 - Could also write pattern a::b::[] as [a;b]
 - a::b::c::d matches lists with at least three elements
 - Matches [1;2;3], binding a to 1, b to 2, c to 3, and d to []
 - Cannot write pattern as [a;b;c]::d (why?)

Pattern Matching – Wildcards

- An underscore is a wildcard pattern
 - Matches anything
 - But doesn't add any bindings
 - Useful to hold a place but discard the value
 - i.e., when the variable does not appear in the branch expression
- In previous examples
 - Many values of h or t ignored
 - Can replace with wildcard __

Pattern Matching – Wildcards (cont.)

Code using

Outputs

To what does the following expression evaluate?

```
match [1;2;3] with
   | 1::[] -> [0]
   | _::_ -> [1]
   | 1:: ::[] -> []
A. []
B. [0]
C. [1]
D. [2;3]
```

To what does the following expression evaluate?

```
match [1;2;3] with
   | 1::[] -> [0]
   | _::_ -> [1]
   | 1:: ::[] -> []
A. []
B. [0]
C. [1]
D. [2;3]
```

Pattern Matching – An Abbreviation

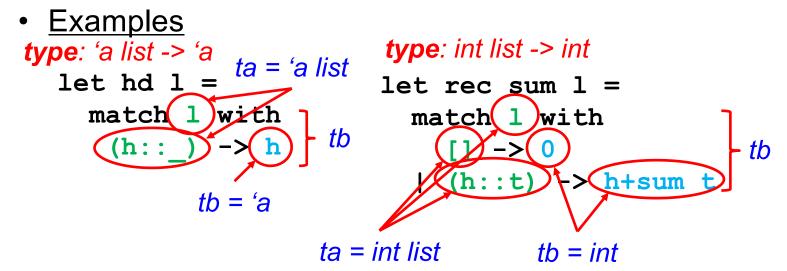

- let f p = e, where p is a pattern
 is shorthand for let f x = match x with p -> e
- Examples

```
- let hd (h::_) = h
- let tl (_::t) = t
- let f (x::y::_) = x + y
- let g [x; y] = x + y
```

· Useful if there's only one acceptable input

Pattern Matching Typing

- match e with
 | p1 -> e1
 | ...
 | pn -> en
- If e and p1, ..., pn each have type ta
- and e1, ..., en each have type tb
- Then entire match expression has type tb

Polymorphic Types

- The sum function works only for int lists
- But the hd function works for any type of list

```
- hd [1; 2; 3] (* returns 1 *)
- hd ["a"; "b"; "c"] (* returns "a" *)
```

OCaml gives such functions polymorphic types

```
- hd : 'a list -> 'a
```

- this says the function takes a list of any element type 'a, and returns something of that same type
- These are basically generic types in Java
 - 'a list is like List<T>

Examples Of Polymorphic Types

```
let tl (::t) = t
   # tl [1; 2; 3];;
   - : int list = [2; 3]
   # tl [1.0; 2.0];;
   - : float list = [2.0]
   (* tl : 'a list -> 'a list *)
• let fst x y = x
   # fst 1 "hello";;
   - : int = 1
   # fst [1; 2] 1;;
   - : int list = [1; 2]
   (* fst : 'a -> 'b -> 'a *)
```

Examples Of Polymorphic Types

```
let eq x y = x = y (* let eq x y = (x = y) *)
# eq 1 2;;
- : bool = false
# eq "hello" "there";;
- : bool = false
# eq "hello" 1 -- type error
(* eq : 'a -> 'a -> bool *)
```

What is the type of the following function?

let
$$f x y =$$
if $x = y$ then 1 else 0

- A. 'a -> 'b -> int
- B. 'a -> 'a -> bool
- C. 'a -> 'a -> int
- D. int

What is the type of the following function?

let
$$f x y =$$

if $x = y$ then 1 else 0

```
A. 'a -> 'b -> int
B. 'a -> 'a -> bool
C. 'a -> 'a -> int
D. int
```

Missing Cases

- Exceptions for inputs that don't match any pattern
 - OCaml will warn you about non-exhaustive matches

Example:

```
# let hd l = match l with (h::_) -> h;;
Warning: this pattern-matching is not exhaustive.
Here is an example of a value that is not matched:
[]
# hd [];;
Exception: Match_failure ("", 1, 11).
```

Pattern matching is **AWESOME**

- 1. You can't forget a case
 - Compiler issues inexhaustive pattern-match warning
- 2. You can't duplicate a case
 - Compiler issues unused match case warning
- 3. You can't get an exception
 - Can't do something like List.hd []
- 4. Pattern matching leads to elegant, concise, beautiful code

Lists and Recursion

- Lists have a recursive structure
 - And so most functions over lists will be recursive

```
let rec length 1 = match 1 with
   [] -> 0
   | (_::t) -> 1 + (length t)
```

- This is just like an inductive definition
 - The length of the empty list is zero
 - The length of a nonempty list is 1 plus the length of the tail
- Type of length?
 - 'a list -> int

More Examples

```
sum 1 (* sum of elts in 1 *)
   let rec sum 1 = match 1 with
        [1 -> 0]
     | (x::xs) \rightarrow x + (sum xs)
   negate 1 (* negate elements in list *)
    let rec negate 1 = match 1 with
       [] <- []
     | (x::xs) -> (-x) :: (negate xs)
   last 1 (* last element of 1 *)
   let rec last 1 = match 1 with
       [x] \rightarrow x
     | (x::xs) \rightarrow last xs
```

More Examples (cont.)

```
(* return a list containing all the elements in the list 1
  followed by all the elements in list m *)

    append 1 m

   let rec append 1 m = match 1 with
      \lceil \rceil -> m
    | (x::xs) -> x::(append xs m)
rev l (* reverse list; hint: use append *)
   let rec rev 1 = match 1 with
       [] <- []
     | (x::xs) -> append (rev xs) (x::[])
```

• rev takes O(n²) time. Can you do better?
