

CMSC 330: Organization of Programming Languages

OCaml Imperative Programming

So Far, Only Functional Programming

- We haven't given you **any** way so far to change something in memory
 - All you can do is create new values from old
- This makes programming easier since it supports mathematical (i.e., **functional**) reasoning
 - Don't care whether data is shared in memory
 - Aliasing is irrelevant
 - Calling a function f with the same argument always produces the same result
 - For all x and y , we have $f\ x = f\ y$ when $x = y$

Imperative OCaml

- Nevertheless, sometimes it is useful for values to change
 - Call a function that returns an *incremented* counter
 - Store aggregations in *efficient* hash tables
- OCaml **variables** are *immutable*, but
- OCaml has **references**, **fields**, and **arrays** that are actually *mutable*
 - I.e., they can **change**

References

- **'a ref**: Pointer to a mutable value of type '**a**
- There are three basic operations on references:

ref : '**a** -> '**a ref**

➤ Allocate a reference

! : '**a ref** -> '**a**

➤ Read the value stored in reference

:= : '**a ref** -> '**a** -> **unit**

➤ Change the value stored in reference

- Binding variable **x** to a reference is **immutable**
 - The **contents of the reference x** points to may change

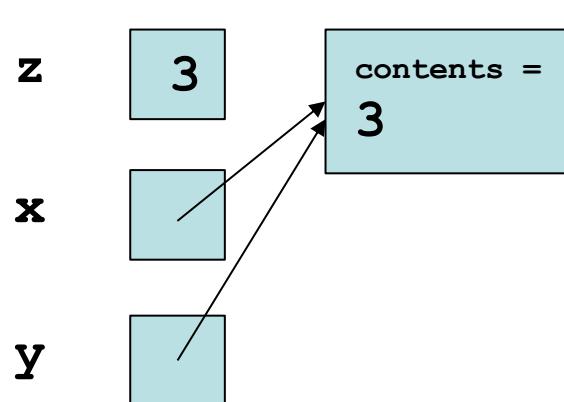

References Usage

Example:

```
# let z = 3;;
val z : int = 3

# let x = ref z;;
val x : int ref = {contents = 3}

# let y = x;;
val y : int ref = {contents = 3}
```

References Usage

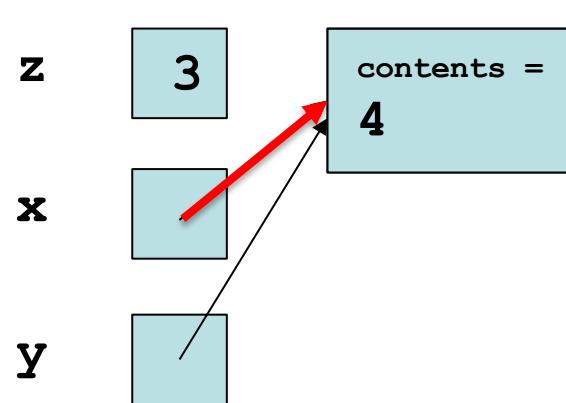

Example:

```
# let z = 3;;
val z : int = 3

# let x = ref z;;
val x : int ref = {contents = 3}

# let y = x;;
val y : int ref = {contents = 3}

# x := 4;;
- : unit = ()
```

References Usage

Example:

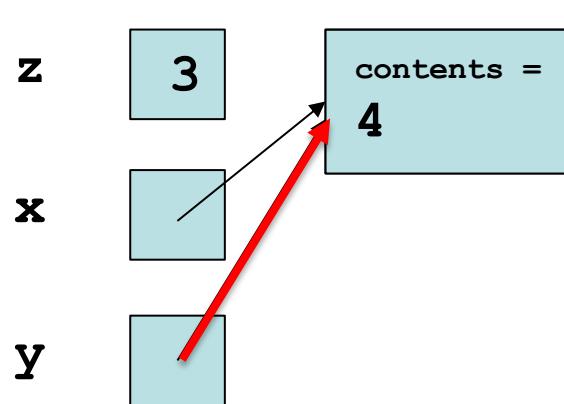

```
# let z = 3;;
val z : int = 3

# let x = ref z;;
val x : int ref = {contents = 3}

# let y = x;;
val y : int ref = {contents = 3}

# x := 4;;
- : unit = ()

# !y;;
- : int = 4
```

Aliasing

- Reconsider our example

```
let z = 3;;
let x = ref z;;
let y = x;;
x := 4;;
!y;;
```

- Here, variables **y** and **x** are **aliases**:
 - In **let y = x**, variable **x** evaluates to a location, and **y** is bound to the **same location**
 - So, changing the contents of that location will cause both **!x** and **!y** to change

Quiz 1: What is the value w?

```
let x = ref 12 in  
let y = ref 13 in  
let z = y in  
let _ = y := 4 in  
let w = !y + !z in  
w
```

- A. 25
- B. 8
- C. 17
- D. 16

Quiz 1: What is the value w?

```
let x = ref 12 in  
let y = ref 13 in  
let z = y in  
let _ = y := 4 in  
let w = !y + !z in  
w
```

- A. 25
- B. 8
- C. 17
- D. 16

Quiz 1a: What is the value w?

```
let x = ref 12 in  
let y = ref 13 in  
let z = !y in  
let _ = y := 4 in  
let w = !y + z in  
w
```

- A. 25
- B. 8
- C. 17
- D. 16

Quiz 1a: What is the value w?

```
let x = ref 12 in  
let y = ref 13 in  
let z = !y in  
let _ = y := 4 in  
let w = !y + z in  
w
```

- A. 25
- B. 8
- C. 17
- D. 16

References: Syntax and Semantics

- Syntax: `ref e`
- Evaluation
 - Evaluate e to a value v
 - Allocate a new location loc in memory to hold v
 - Store v in contents of memory at loc
 - Return loc (which is itself a value)
- Type checking
 - $(\text{ref } e) : t \text{ ref}$
 - if $e : t$

References: Syntax and Semantics

- Syntax: $e1 := e2$
- Evaluation
 - Evaluate $e2$ to a value $v2$
 - Evaluate $e1$ to a location loc
 - Store $v2$ in contents of memory at loc
 - Return ()
- Type checking
 - $(e1 := e2) : \text{unit}$
 - if $e1 : t \text{ ref}$ and $e2 : t$

References: Syntax and Semantics

- **Syntax:** $!e$
 - *This is not negation. Operator ! is like operator * in C*
- **Evaluation**
 - Evaluate e to a location loc
 - Return contents v of memory at loc
- **Type checking**
 - $!e : t$
 - if $e : t \text{ ref}$

Sequences: Syntax and Semantics

- Syntax: $e_1; e_2$
 - $e_1; e_2$ is the same as `let () = e1 in e2`
- Evaluation
 - Evaluate e_1 to a value v_1
 - Evaluate e_2 to a value v_2
 - Return v_2
 - Throws away v_1 – so e_1 is useful only if it has *side effects*, e.g., if it modifies a reference's contents or accesses a file
- Type checking
 - $e_1; e_2 : t$
 - if $e_1 : \text{unit}$ and $e_2 : t$

;; versus ;

- `;;` ends an expression in the top-level of OCaml
 - Use it to say: “Give me the value of this expression”
 - Not used in the body of a function
 - Not needed after each function definition
 - Though for now it won’t hurt if used there
- $e_1; e_2$ evaluates e_1 and then e_2 , and returns e_2

```
let print_both (s, t) = print_string s; print_string t;  
                      "Printed s and t"
```

- notice no `;` at end – it’s a **separator**, not a **terminator**

```
print_both ("Colorless green ", "ideas sleep")
```

Prints `"Colorless green ideas sleep"`, and returns

`"Printed s and t"`

Grouping Sequences

- If you're not sure about the scoping rules, use `begin...end`, or *parentheses*, to group together statements with semicolons

```
let x = ref 0
let f () =
  begin
    print_string "hello";
    x := !x + 1
  end
```

```
let x = ref 0
let f () =
(
  print_string "hello";
  x := !x + 1
)
```

Implement a Counter

```
# let counter = ref 0 ;;
val counter : int ref = { contents=0 }

# let next =
  fun () ->
    counter := !counter + 1; !counter ;;
val next : unit -> int = <fun>

# next ();;
- : int = 1

# next ();;
- : int = 2
```

Hide the Reference

```
# let next =
  let counter = ref 0 in
  fun () ->
    counter := !counter + 1; !counter ;;
val next : unit -> int = <fun>

# next ();;
- : int = 1

# next ();;
- : int = 2
```

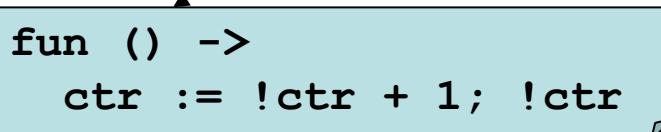

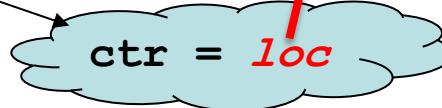

Hide the Reference, Visualized

```
let next =
  let ctr = ref 0 in
    fun () ->
      ctr := !ctr + 1; !ctr
```

→

```
let next =
  let ctr = loc in
    fun () ->
      ctr := !ctr + 1; !ctr
```

→

```
let next = 
  
    
      a closure
```

Quiz 2: What is wrong with the counter?

```
let next =
    fun () ->
        let counter = ref 0 in
        counter := !counter + 1;
        !counter
```

- A. It returns a boolean, not an integer
- B. It returns the same integer every time
- C. It returns a reference to an integer instead of an integer
- D. Nothing is wrong

Quiz 2: What is wrong with the counter?

```
let next =
    fun () ->
        let counter = ref 0 in
        counter := !counter + 1;
        !counter
```

- A. It returns a boolean, not an integer
- B. It returns the same integer every time
- C. It returns a reference to an integer instead of an integer
- D. Nothing is wrong

The Trade-Off Of Side Effects

- Side effects are absolutely necessary
 - That's usually why we run software! We want something to happen that we can observe
- They also make reasoning harder
 - Order of evaluation now matters
 - No referential transparency
 - Calling the same function with the same arguments may produce different results
 - Aliasing may result in hard-to-understand bugs
 - If we call a function with refs `r1` and `r2`, it might do strange things if `r1` and `r2` are aliases

Order of Evaluation

- Consider this example

```
let y = ref 1;;
let f _ z = z+1;; (* ignores first arg *)
let w = f (y:=2) !y;;
w;;
```

- The **first argument** to the call to **f** is the result of the assignment expression **y:=2**, which is unit **()**
 - The **second argument** is the current contents of reference **y**
- What is **w** if **f**'s arguments are evaluated **left to right**?
 - 3
- What if they are evaluated **right to left**?
 - 2

OCaml Order of Evaluation

- In OCaml, the order of evaluation is **unspecified**
 - This means that the language doesn't take a stand, and different implementations may do different things
- On my Mac, OCaml evaluates **right to left**
 - True for the bytecode interpreter and x86 native code
 - Run the previous example and see for yourself!
- Strive to make your programs produce **the same answer regardless of evaluation order**

Quiz 3: Will w's value differ

If evaluation order is left to right, rather than right to left?

```
let y      =  ref 1 in  
let f z =  z := !z+1; !z in  
let w      =  (f y) + (f y) in
```

w

- A. True
- B. False

Quiz 3: Will w's value differ

If evaluation order is left to right, rather than right to left?

```
let y      =  ref 1 in  
let f z =  z := !z+1; !z in  
let w      =  (f y) + (f y) in
```

w

- A. True
- B. False

Quiz 4: Will w's value differ

If evaluation order is left to right, rather than right to left?

```
let y      =  ref 1 in  
let f z =  z := !z+1; !z in  
let w      =  (f y) + !y in
```

w

- A. True
- B. False

Quiz 4: Will w's value differ

If evaluation order is left to right, rather than right to left?

```
let y      =  ref 1 in  
let f z =  z := !z+1; !z in  
let w      =  (f y) + !y in  
w
```

- A. True
- B. False

Quiz 5: Which **f** is **not** referentially transparent?

i.e., not the case that $f\ x = f\ y$ for all $x = y$

A. `let f z =
 let y = ref z in
 y := !y + z;
 !y`

C. `let f z =
 let y = z in
 y+z`

B. `let f =
 let y = ref 0 in
 fun z ->
 y := !y + z; !y`

D. `let f z = z+1`

Quiz 5: Which **f** is not referentially transparent?

i.e., not the case that $f\ x = f\ y$ for all $x = y$

A. `let f z =
 let y = ref z in
 y := !y + z;
 !y`

B. `let f =
 let y = ref 0 in
 fun z ->
 y := !y + z; !y`

C. `let f z =
 let y = z in
 y+z`

D. `let f z = z+1`

This is basically the **counter** function

Structural vs. Physical Equality

- The `=` operator compares objects structurally
 - The `<>` operator is the negation of structural equality
- The `==` operator compares objects physically
 - The `!=` operator is the negation of physical equality
- Examples
 - $([1;2;3] = [1;2;3]) = \text{true}$ $([1;2;3] <> [1;2;3]) = \text{false}$
 - $([1;2;3] == [1;2;3]) = \text{false}$ $([1;2;3] != [1;2;3]) = \text{true}$
- Mostly you want to use `=` and `<>`
 - E.g., the `=` operator is used for pattern matching
- But `=` is a problem with **cyclic data structures**

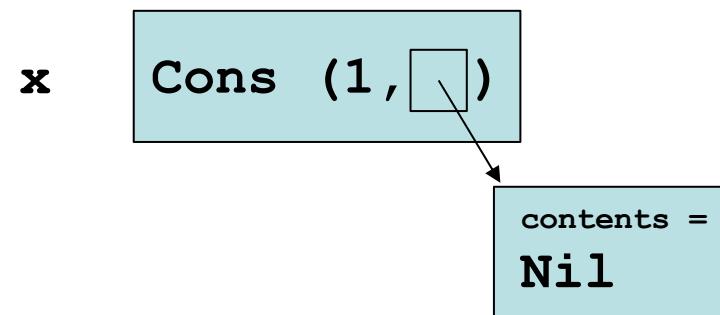

Cyclic Data Structures Possible With Ref

```
type 'a rlist =
  Nil | Cons of 'a * ('a rlist ref);;

let newcell x y = Cons(x,ref y);;

let updnext (Cons (_ ,r)) y = r := y;;
```

```
# let x = newcell 1 Nil;;
val x : int reflist = Cons (1, {contents = Nil})
```

Cyclic Data Structures Possible With Ref

```
type 'a rlist =
    Nil | Cons of 'a * ('a rlist ref);;

let newcell x y = Cons(x,ref y);;

let updnext (Cons (_ ,r)) y = r := y;;
```

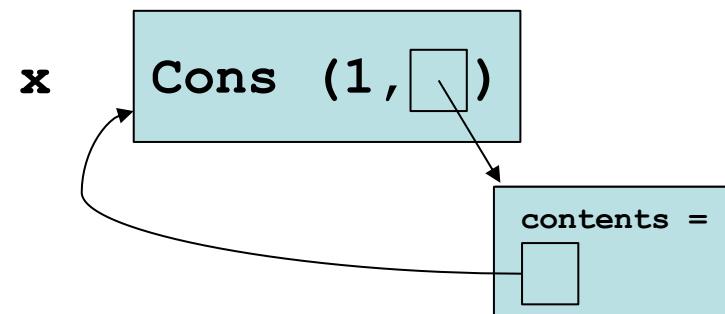

```
# let x = newcell 1 Nil;;
val x : int ref list = Cons (1, {contents = Nil})

# updnext x x;;
- : unit = ()

# x == x;;
- : bool = true

# x = x;; (* hangs *)
```

Equality of refs themselves

- Refs are compared **structurally** by their **contents**,
physically by their addresses
 - `ref 1 = ref 1` (* true *)
 - `ref 1 <> ref 2` (* true *)
 - `ref 1 != ref 1` (* true *)
 - `let x = ref 1 in x == x` (* true *)

Mutable fields

- Fields of a record type can be declared as mutable:

```
# type point = {x:int; y:int; mutable c:string};;
type point = { x : int; y : int; mutable c : string; }

# let p = {x=0; y=0; c="red"};;
val p : point = {x = 0; y = 0; c = "red"}

# p.c <- "white";;
- : unit = ()

# p;;
val p : point = {x = 0; y = 0; c = "white"}

# p.x <- 3;;
Error: The record field x is not mutable
```

Implementing Refs

- Ref cells are essentially syntactic sugar:

```
type 'a ref = { mutable contents: 'a }

let ref x = { contents = x }

let (!) r = r.contents

let (:=) r newval = r.contents <- newval
```

- ref type is declared in **Pervasives**
- ref functions are compiled to equivalents of above

Arrays

- **Arrays** generalize ref cells from a single mutable value to a sequence of mutable values

```
# let v = [|0.; 1.|];;
val v : float array = [|0.; 1.|]

# v.(0) <- 5.;;
- : unit = ()

# v;;
- : float array = [|5.; 1.|]
```

Arrays

- Syntax: $[| e_1; \dots; e_n |]$
- Evaluation
 - Evaluates to an n -element array, whose elements are initialized to $v_1 \dots v_n$, where e_1 evaluates to v_1 , ..., e_n evaluates to v_n
 - Evaluates them *right to left*
- Type checking
 - $[| e_1; \dots; e_n |] : t \text{ array}$
 - If for all i , each $e_i : t$

Arrays

- Syntax: $e1 . (e2)$
- Evaluation
 - Evaluate $e2$ to integer value $v2$
 - Evaluate $e1$ to array value $v1$
 - If $0 \leq v2 < n$, where n is the length of array $v1$, then return element at offset $v2$ of $v1$
 - Else raise Invalid_argument exception
- Type checking: $e1 . (e2) : t$
 - if $e1 : t$ array and $e2 : \text{int}$

Arrays

- Syntax: $e1. (e2) \leftarrow e3$
- Evaluation
 - Evaluate $e3$ to $v3$
 - Evaluate $e2$ to integer value $v2$
 - Evaluate $e1$ to array value $v1$
 - If $0 \leq v2 < n$, where n is the length of array $v1$, then update element at offset $v2$ of $v1$ to $v3$
 - Else raise `Invalid_argument` exception
 - Return ()
- Type checking: $e1. (e2) \leftarrow e3 : \text{unit}$
 - if $e1 : t_{\text{array}}$ and $e2 : \text{int}$ and $e3 : t$

Quiz 6: What does this evaluate to?

```
let x = [| 0; 1 |] in  
let w = x in  
x.(0) <- 1;  
x == w
```

- A. ()
- B. true
- C. false
- D. *Type error*

Quiz 6: What does this evaluate to?

```
let x = [| 0; 1 |] in  
let w = x in  
x.(0) <- 1;  
x == w
```

- A. ()
- B. **true – they point to the same array**
- C. false
- D. *Type error*

Control structures

- Traditional loop structures are useful with imperative features:

while e_1 do e_2 done

for $x=e_1$ to e_2 do e_3 done

for $x=e_1$ downto e_2 do e_3 done
