## Closures and Iterators In Rust

# Using Closures/Functions Locally

---

- Rust has local functions, and closures

```
fn moveit(l:bool,x:i32) -> i32 {  
  let left = |x| x - 1;  
  fn right(x:i32) -> i32 { x+1 };  
  if l { left(x) }  
  else { right(x) }  
}
```

Closure (may  
have an  
environment)

Local function  
(no  
environment)

- OCaml local functions/closures

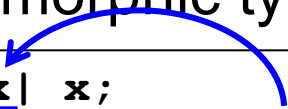

```
let moveit l x =  
  let left = fun x -> x - 1 in  
  let right = fun x -> x + 1 in  
  if l then left x  
  else right x
```

# Limits of Type Inference

---

- Rust infers non-polymorphic types

```
let id = |x| x;  
let x = id(1); //infers x:i32  
let y = id("hi"); //fails: &str ≠ i32
```

- OCaml infers polymorphic types

```
let f = fun x -> x in (* 'a -> 'a *)  
let x = id 1 in  
let y = id "hi" in (* OK *) ...
```

- More details on closures at the end, including polymorphism
  - Now for something (not so completely) different

# Iteration using the `Iterator` Trait

---

- Recall an earlier example:

```
let a = vec![10, 20, 30, 40, 50];
for e in a.iter() {
    println!("the value is: {}", e);
}
```

- The `iter()` method returns an *iterator*, i.e., a value with the `Iterator` trait

```
trait Iterator {
    type Item; //this is an associated type
    fn next(&mut self) -> Option<Self::Item>;
    ... //default method impls
}
```

# Unpacking the `for` syntax

---

- Each call to `next` advances the iterator
  - So it has to be `mut`

```
let a = vec![10, 20];
let mut iter = a.iter();
assert_eq!(iter.next(), Some(&10));
assert_eq!(iter.next(), Some(&20));
assert_eq!(iter.next(), None);
```

- calls to `next` produce **immutable references** to the values in `a`
  - else may call `into_iter` or `iter_mut` on `a` to get different sorts of references

# Iterator Adaptors

---

- We can make one iterator from another
  - An iterator is **consumed as it used**; it is *lazy*
- This is a pattern for higher order programming
  - `i.map(f)` produces an iterator returning `f(e)` for each of `i`'s elements `e`
  - `i.filter(f)` produces iterator for `i`'s elements `e` such that `f(e) == true`
  - `i.collect()` converts an iterator into a vector
  - `i.fold(a, f)` is like OCaml's `fold_right`
    - `fold_right f a v` where `v` is the list corresponding to `i`
  - `zip`, `sum`, ...

# Examples

---

```
let a = vec![10,20];
let i = a.iter();
let j = i.map(|x| x+1).collect();
//[11,21]
let k = a.iter().fold(0,|a,x| x-a); //10
for e in a.iter().filter(|&&x| x == 10) {
    println!("{}",e);
} //prints 10
```

# Quiz 1: Output of the following code

---

```
fn main() {  
    let a = [0, 1, 2, 3, 4, 5];  
    let mut iter2 = a.iter().map(|x| 2 * x);  
    iter2.next();  
    let t2 = iter2.next();  
    println!("{:?}", t2)  
}
```

- A. Some(0)
- B. Some(1)
- C. Some(2)
- D. Some(4)

# Quiz 1: Output of the following code

---

```
fn main() {  
    let a = [0, 1, 2, 3, 4, 5];  
    let mut iter2 = a.iter().map(|x| 2 * x);  
    iter2.next();  
    let t2 = iter2.next();  
    println!("{:?}", t2)  
}
```

- A. Some(0)
- B. Some(1)
- C. Some(2)
- D. Some(4)

# Iterator Notes

---

- You can make your own iterators too
  - Implement the Iterator trait
  - Several examples in the Rust Book
- Iterators perform extremely well
  - Better than for loops with explicit indexes!
  - This is because Rust aggressively optimizes the code it generates, e.g., by unrolling the iteration loop
  - So feel free to program using map, fold, zip, etc.

# Iter Example

---

```
struct Fibonacci {
    curr: u32,
    next: u32,
}

impl Iterator for Fibonacci {
    type Item = u32;
    fn next(&mut self) -> Option<Self::Item> {
        let new_next = self.curr + self.next;
        self.curr = self.next;
        self.next = new_next;

        if self.curr < 100 {
            Some(self.curr)
        }else{
            return None
        }
    }
}

fn fibonacci() -> Fibonacci {
    Fibonacci { curr: 0, next: 1 }
}
```

```
fn main() {
    println!("The first 15 terms of the Fibonacci seq:");
    for i in fibonacci().take(15) {
        print!("{}", i);
    }

    println!("\nfrom 5th, the next 3 terms of the Fibonacci seq:");
    for i in fibonacci().skip(4).take(3){
        print!("{}", i);
    }
    println!()
}
```

# Back to Closures: Passing as Arguments

---

- Each closure has a distinct type
  - Even if two closures have the **same signature**, their **types are considered different**
    - Such types are called *generative* types
- To specify the **type of a closure** (for a function parameter, say), use **generics with trait bounds**
  - **Fn** *t* *(will describe later)*
  - **FnMut** *t*
  - **FnOnce** *t*
- Functions (defined with **fn** *f*...) implement the above trait bounds too

# Using the Fn Trait

Trait bound on  $\mathbb{T}$  to  
specify type of  $f$

```
fn app_int<T>(f:T,x:i32) -> i32
    where T:Fn(i32) -> i32
{
    f(x)
}
fn main() {
    println!("{}",app_int((|x| x-1),1));
}
```

– But cannot write

```
fn app_int(f:(i32) -> i32,x:i32) -> i32
{ f(x) }
```

- Can also use function trait bounds in struct, enum, etc. definitions

# Using the Fn Trait Polymorphically

---

```
fn app<T,U,W>(f:T,x:U) -> W
    where T:Fn(U) -> W
{
    f(x)
}
fn main() {
    println!("{}",app(|x| x-1),1);//i32
    let s = String::from("hi ");
    println!("{}",app(|x| x+"there",s));//String
}
```

# Capturing Free Variables

---

```
fn main() {  
    let x = 4;  
    let equal_to_x = |z| z == x;  
    let y = 4;  
    assert!(equal_to_x(y))  
} // true
```

Closure  
env  
captures **x**

- Note: fails if `equal_to_x` defined as a local function
  - Local functions do not have an environment
- Complication: What if `x` is owned?
  - Capturing it could move it or borrow (mut or immut)
  - Use various `FnX` traits to specify what to do

# Distinguishing Fn Trait Bounds

---

- **FnOnce** *t* (where *t* is a func type)
  - Consumes the variables it captures from its enclosing scope (i.e., moves or copies them)
  - Thus can only be called once
    - The call consumes ownership
- **FnMut** *t*
  - Borrows captured variables mutably
- **Fn** *t*
  - Borrows captured variables immutably, or copies
    - `equal_to_x` copied `x` due to its `Copy` trait
  - Try this bound first; follow the compiler's advice if it doesn't work

# Example use of FnOnce

---

```
let x = String::from("hi");  
let add_x = |z| x+z; //captures x; is FnOnce  
println!("{}",x); //fails  
let s = add_x(" there"); //consumes closure  
let t = add_x(" joe"); //fails, add_x consumed
```
