

# Computer Systems Architecture CMSC 411 Unit 1 – Computer Design and Evaluation

Alan Sussman  
January 28, 2003

## Administrivia

- Class web pages are at <http://www.cs.umd.edu/class/spring2003/cmssc411-0301>  
– and linked in from CS dept. class web pages
- Class accounts for project will be on CSIC Linux cluster
- First homework, for Unit 1, handed out Thursday, 1/30
- Start reading Ch. 1 of H&P

CMSC 411 - Alan Sussman

2

## Introduction

- Why are you taking this course?
  - You really liked the material in 311 and want to learn more?
  - The course time fit into your schedule well?
  - You needed upper level CS courses and chose this one at random?
  - All the courses you really wanted to take were filled?

CMSC 411 - Alan Sussman

3

## What can you expect to learn in this course?

- What to look for in buying a PC (brag to parents and friends!).
- How computer architecture affects programming style.
- Variations on interconnection networks.
- A great deal of jargon.

CMSC 411 - Alan Sussman

4

## Syllabus

- More on web page
- Importance of *doing the homework*.
- Lecture notes available on the web. You can print them before coming to class and then add your own notes (if I put them up in time).
- I'll correct any typos/errors after each lecture and re-post

CMSC 411 - Alan Sussman

5

## The Textbook – H&P

- Everyone complains about it.
- Virtually all of the top schools use it.
- You can handle it, but you have to work at it – *do the reading*
- Through lecture notes, other references, and edits, I'll try to help you put it all together.

CMSC 411 - Alan Sussman

6

## Chapter 1 of H&P

- Read Chapter 1; you can skip the economics of *cost vs. price*.
- Historical Perspective - Section 1.10
  - Computers as we know them are roughly 55 years old.
  - The *von Neumann machine* model that underlies computer design is only partially von Neumann's.
  - Why does Konrad Zuse say he had "the bad luck of being too early"?
    - Optional: Read his own recollections in TR 180 of ETH, Zürich, <http://www.inf.ethz.ch/research/publications/show.php?what=180&lang=en&type=tr> (contains both German and English)
  - No one was able to successfully patent the idea of a stored-program computer, much to the dismay of Eckert and Mauchly.

CMSC 411 - Alan Sussman

7

## Early development steps

- Make input and output easier than wiring circuit boards and reading lights.
- Make programming more easy by developing higher level programming languages, so that users did not need to use binary machine code instructions.
- Develop storage devices.

CMSC 411 - Alan Sussman

8

## Later development steps

- Faster
- More storage
- Cheaper
- Networking and parallel computing
- Better user interfaces
- Ubiquitous applications
- Development of standards

CMSC 411 - Alan Sussman

9

## Perspective: An example

- Most powerful computer in 1988: CRAY Y-MP.
- 1993: a desktop workstation (IBM Power-2) matched its power at less than 10% of the cost.
- How did this happen?
  - hardware improvements, e.g., squeezing more circuits into a smaller area.
  - improvements in instruction-set design, e.g., making the machine faster on a small number of frequently used instructions.
  - improvements in compilation, e.g., optimizing code to reduce memory accesses and make use of faster machine instructions.

CMSC 411 - Alan Sussman

10

## Computer Architecture

- instruction set architecture:
  - which elementary instructions are basic to programming the machine.
- organization:
  - memory systems to store information,
  - bus systems to move information,
  - logical design of CPU (recall from 311).
- hardware:
  - what physical components are used to form the computer.

CMSC 411 - Alan Sussman

11

## Why a computer scientist should care

- to choose an architecture that matches a user's needs.
- to compare and benchmark different computers.
- to decide whether an upgrade is cost-efficient.
- to write a program that exploits the strengths of a given computer.

CMSC 411 - Alan Sussman

12

## Technology is rapidly changing

- From Sections 1.3 & 1.4
  - The average program hogs twice as much memory each year.
    - Example: Microsoft
  - Transistor density increases by 50% each year.
  - Dynamic random access memory (DRAM) density increases by 60% each year.
  - Disk density increases by 50% each year.
  - Lifespan of a computer is about 5 years.
  - Cost of DRAM drops by about 40% each year.

CMSC 411 - Alan Sussman

13

## Costs

- From Figure 1.9 in H&P
- The cost of components in a \$1000 PC in 2001 are:
  - CPU – 22%
  - Monitor – 19%
  - Hard drive – only 9%
  - DRAM – only 5% (for 128MB)
  - Software – 20% (OS & basic office suite)

CMSC 411 - Alan Sussman

14

## Manufacture of DRAM and other chips

- Chips are manufactured on **wafers** - circular disks containing many dies (chips).
- The wafer is tested and chopped into **dies**.

© 2000 Elsevier Science B.V. All rights reserved.

CMSC 411 - Alan Sussman

15

## Wafers and dies

- To find the cost of a die:
  - Number of dies per wafer is *at most* the area of the wafer divided by the area of the die.
  - The cost of the wafer divided by the number of **working** dies per wafer is the cost of each die.
- The fraction of working dies is called the *die yield*, which decreases as the area of the die increases.
- Rule of thumb (p. 20): Cost of die is proportional to the square of the die area

CMSC 411 - Alan Sussman

16

## Comparing performance of two machines

- Definition: **Performance** is equal to 1 divided by execution time.
- Problem: How to measure execution time?

CMSC 411 - Alan Sussman

17

## What is time?

- Unix time command example (p.26):
  - 90.7u 12.9s 2:39 65%
  - The user used the CPU for 90.7 seconds (user CPU time).
  - The system used it for 12.9 seconds (system CPU time).
  - Elapsed time from the user's request to completion of the task was 2 minutes, 39 seconds (159 seconds).
  - And  $(90.7 + 12.9)/159 = 65\%$ . The rest of the time was spent waiting for I/O or running other programs.

CMSC 411 - Alan Sussman

18

## Time (cont.)

- Usual measurements of time:
  - **system performance** measures the elapsed time on unloaded (single user) system.
  - **CPU performance** measures user CPU time on unloaded system.

CMSC 411 - Alan Sussman

19

## How to measure CPU performance

- **Benchmark:** a program used to measure performance.
  - real programs - what is reality?
  - kernels - loops in which most of time is spent in a real program
  - toy programs
  - synthetic programs
- Fact: Computer manufacturers tune their product to the popular benchmarks. "Your results may vary," unless you run benchmark programs and nothing else. See Figure 1.12 listing programs in the SPEC CPU2000 benchmark suite

CMSC 411 - Alan Sussman

20

## Computer Systems Architecture CMSC 411 Unit 1 – Computer Design and Evaluation

Alan Sussman  
January 30, 2003

## Administrivia

- Homework #1 posted
  - H&P 1.3 (a,b), 1.7 (a-c), 1.11, 1.17(a-d)
  - due in one week, in class - Feb. 6

CMSC 411 - Alan Sussman

22

## Last time

- Computer architecture is:
  - Instruction set arch. (ISA), organization, hardware
- Have to deal with rapidly changing technology
  - Transistor, DRAM, disk density all increasing very rapidly (50-60%/year), and cost dropping
- Cost of a die on a wafer proportional to square of die area
- Performance = 1/(execution time)
  - System performance is elapsed time
  - CPU performance is user CPU time
- Benchmarks
  - Real programs vs. kernels vs. toy or synthetic programs

CMSC 411 - Alan Sussman

23

## Reproducibility

- Benchmarking is a laboratory experiment, and needs to be documented as fully as a well-run chemistry experiment.
  - Identify each variable hardware component.
  - Identify compiler flags and measure variability.
  - Verify reproducibility and provide data for others to reproduce the benchmarking results.

CMSC 411 - Alan Sussman

24

## Reporting results

- Example of parameters for SPEC CINT2000 benchmark is in H&P Figure 1.14
  - for a Dell workstation running Windows NT4.0
  - data on hardware - CPU (how many, primary and secondary caches), memory, disk
  - data on software – OS, compilers, file system type, and compiler flags used (very important!)
- How to summarize results?

CMSC 411 - Alan Sussman

25

## Sample results

From Figure 1.15 in H&P – which machine is fastest?

|                  | Computer A | Computer B | Computer C |
|------------------|------------|------------|------------|
| Program P1 (sec) | 1          | 10         | 20         |
| Program P2 (sec) | 1000       | 100        | 20         |
| Program P3 (sec) | 1001       | 110        | 40         |

CMSC 411 - Alan Sussman

26

## Statistical reporting

- “It is rare indeed when advertisers, politicians, pop economists, and drumbeaters for medical programs offer a statistical argument that is not either misleading or downright deceptive.” - Martin Gardner
- “... in mathematics you don't understand things, you just get used to them.” - John von Neumann
- “... if you torture your data long enough, they will tell you what you want to hear.” - James L. Mills, M.D.

CMSC 411 - Alan Sussman

27

## Statistical reporting (cont.)

- The **average** execution time is the **arithmetic mean**:
  - sum the execution times for each program and divide by the number of programs  $n$ .
- The **harmonic mean** is  $n$  divided by the sum of some function of each execution time.
- Often, both of these means are modified to give more weight to more important programs.

CMSC 411 - Alan Sussman

28

## Statistical reporting (cont.)

- The arithmetic mean is good if the weights represent your own workload. Then you can compare how each machine will perform for you.
  - Don't set the weights based on performance on any particular machine; Figure 1.16 illustrates confusing results obtained by doing this.
- The harmonic mean gives the same sort of information, but is used when rates (e.g., instructions per second) are measured instead of times.

CMSC 411 - Alan Sussman

29

## Geometric mean

- To measure relative performance, use the **geometric mean**.
  - Choose a *reference machine*, divide all execution times by the corresponding times on the reference machine, multiply these ratios together, and take the  $n$ th root of the product.
- Geometric means have the nice property that you get consistent results regardless of which machine is used to normalize (Figure 1.17)

CMSC 411 - Alan Sussman

30

## How to make computers faster

- **Make the common case faster!**
- Example: Put more effort and funds into optimizing the hardware for addition than to optimize square root.
- **Amdahl's law** quantifies this principle:
  - Define **speedup** as the time the task took originally divided by the time the task takes after improvement.

CMSC 411 - Alan Sussman

31

## Amdahl's Law

- Then Amdahl tells us what the speedup of a particular task is, given
  - fraction  $f$  of the original execution time that the task could use the improvement
  - the speedup  $s$  of a task that always uses the improvement.
- Then what is the speedup of the task?

CMSC 411 - Alan Sussman

32

## Amdahl's Law (cont.)

- Suppose that the original task runs for 1 second. It takes  $f$  seconds in the critical piece, and  $1-f$  in other things.
- Then the task on the improved machine will take only  $f/s$  seconds in the critical piece, but will still take  $1-f$  seconds in other things.
- $\text{speedup} = \frac{\text{old\_time}}{\text{new\_time}} = \frac{1}{1 - f + \frac{f}{s}}$

CMSC 411 - Alan Sussman

33

## Example 1

- Suppose we work very hard improving the square root hardware, and suppose that our task originally spends 1% of its time doing square roots. Even if our improvement reduces the square root time to zero, our speedup is no better than
- $\text{speedup} = \frac{1}{1 - f} = \frac{1}{.99} = 1.01$
- *And we might be better off putting our effort into a more important part of the task.*

CMSC 411 - Alan Sussman

34

## Example 2

- Suppose that, for the same cost, we can speed up integer arithmetic by a factor of 20, or speed up floating point arithmetic by a factor of 2. If our task spends 10% of its time in integer arithmetic, and 40% of its time in floating point arithmetic, which should we do?

CMSC 411 - Alan Sussman

35

## Example 2 (cont.)

- Option 1:  
 $\text{speedup} = \frac{1}{.9 + \frac{.1}{20}} = 1.105$
- Option 2:  
 $\text{speedup} = \frac{1}{.6 + \frac{.4}{2}} = 1.25$

CMSC 411 - Alan Sussman

36

## CPU Performance

- More jargon ...
- Something new happens in a computer during every **clock cycle**.
- The clock rate is what manufacturers usually advertise to indicate a chip's speed:
  - e.g., a 1.2GHz Pentium 4.
- But how fast the machine is depends on the clock rate *and* the number of clock cycles per instruction (CPI)

CMSC 411 - Alan Sussman

37

## CPU Performance (cont.)

- So total CPU time = instruction count (IC) times CPI divided by clock rate (MHz/GHz).
  - $IC * CPI / MHz$
- There's an example on p. 44 that illustrates the overall effect
- Note: CPI is not a good measure of performance since it varies by type of instruction!

CMSC 411 - Alan Sussman

38

## How to design a fast computer

- Amdahl's law says put your effort into optimizing instructions that are often used.
- **The locality of reference** rule-of-thumb says that a program spends 90% of its time in 10% of the code, so we should put effort into taking advantage of this, through a **memory hierarchy**.
- For data accesses, 2 types of locality
  - temporal
  - spatial

CMSC 411 - Alan Sussman

39

## Take advantage of parallelism

- At system level
  - e.g., use multiple CPUs (Unit 7), disks (Unit 6)
- At processor level
  - among instructions (Unit 4)
  - e.g., pipelining (Unit 3)
- At digital design level
  - e.g., set associative caches (Unit 5), carry-lookahead in ALU design

CMSC 411 - Alan Sussman

40

## Performance/Price Performance

For desktop systems (H&P Figure 1.18) – 512MB ECC SDRAM, July 2001

| Model              | Processor       | Clock rate (MHz) | Price    |
|--------------------|-----------------|------------------|----------|
| Compaq 7000        | AMD Athlon      | 1400             | \$2091   |
| Dell 420           | Pentium III     | 1000             | \$3834   |
| Dell 530           | Pentium 4       | 1700             | \$4175   |
| HP c3600           | PA 8600         | 552              | \$12,631 |
| IBM RS6000 44P/170 | IBM Power III-2 | 450              | \$13,889 |
| Sunblade 100       | UltraSPARC II-e | 500              | \$2950   |
| Sunblade 1000      | UltraSPARC III  | 750              | \$9950   |

CMSC 411 - Alan Sussman

43

## Performance/Price Performance

- For OLTP systems
- See Figure 1.21 (and [www.tpc.org](http://www.tpc.org)) for system details
  - both high total performance, and high price performance systems
- No uniprocessor systems
  - one cluster (IBM with 280 Pentium IIIs)
  - others multiprocessors (SMPs)

CMSC 411 - Alan Sussman

44

## High performing OLTP systems

H&P Figure 1.22

CMSC 411 - Alan Sussman

46

## Fallacies

- MIPS (Millions of Instructions Per Second) or MFLOPS (Millions of Floating Point Operations) is a good way to compare performance.
- **Fallacy:** One computer may have more powerful instructions than another, and MIPS/MFLOPS depends on the instruction mix that you choose.

CMSC 411 - Alan Sussman

47

## Fallacies (cont.)

- Relative performance of 2 processors with same ISA can be judged by clock rate or by single benchmark suite
- **Fallacy:** other factors matter too, e.g., pipeline structure, memory system

CMSC 411 - Alan Sussman

48

## Fallacies (cont.)

- Synthetic benchmarks predict performance of real programs.
- **Fallacy:** they don't reflect program behavior for factors not measured, and are very susceptible to compiler and hardware optimizations that may not work on real programs.

CMSC 411 - Alan Sussman

49

## Fallacies (cont.)

- Benchmarks remain valid indefinitely.
- **Fallacy:** Needs change, hardware changes, languages change, compilers change (esp. better optimization), ...

CMSC 411 - Alan Sussman

50

## Fallacies (cont.)

- Peak performance tracks observed performance
- **Fallacy:** Peak performance is a speed limit, the *guaranteed-not-to-be-exceeded* performance, and virtually never seen in practice.

CMSC 411 - Alan Sussman

51

## Pitfalls

- Comparing hand-coded assembly and compiler-generated high-level language performance
- **Pitfall:** hand-coding most applications not possible – because of high software development costs – even though it is possible for key loops, performance critical kernels

CMSC 411 - Alan Sussman

52

## Pitfalls (cont.)

- Neglecting software costs in evaluating a system or for cost-performance analysis
- **Pitfall:** software costs can be a large fraction of both purchase cost and operational (maintenance) costs of a system
  - e.g., Microsoft Windows + Office costs ~\$300 for a PC system with hardware costing ~\$1000, so software costs are ~25% of the total cost (and higher if not bundled with the hardware)

CMSC 411 - Alan Sussman

53
