

# CMSC 330: Organization of Programming Languages

## Objects and Functional Programming

CMSC 330

1

## OOP vs. FP

- ▶ Object-oriented programming (OOP)
  - Computation as interactions between objects
  - Objects encapsulate state, which is usually mutable
    - Accessed / modified via object's public methods
- ▶ Functional programming (FP)
  - Computation as evaluation of functions
    - Mutable data used to improve efficiency
  - Higher-order functions implemented as closures
    - Closure = function + environment

CMSC 330

2

## Relating Objects to Closures

- ▶ An object...
  - Is a collection of fields (data)
  - ...and methods (code)
  - When a method is invoked
    - Method has implicit **this** parameter that can be used to access fields of object
- ▶ A closure...
  - Is a pointer to an environment (data)
  - ...and a function body (code)
  - When a closure is invoked
    - Function has implicit environment that can be used to access variables

CMSC 330

3

## Relating Objects to Closures (cont.)

```
class C {
  int x = 0;
  void set_x(int y) { x = y; }
  int get_x() { return x; }
}
```

```
let make () =
  let x = ref 0 in
  ( (fun y -> x := y),
    (fun () -> !x) )
```

`C c = new C();`  
`c.set_x(3);`  
`int y = c.get_x();`

`fun y -> x := y`    `fun () -> !x`

```
let (set, get) = make ();;
set 3;;
let y = get ();;
```

CMSC 330

4

## Encoding Objects with Closures

- ▶ We can apply this transformation in general

```
class C { f1 ... fn; m1 ... mn; }
```

- becomes

```
let make () =
  let f1 = ...
  ...
  and fn = ... in
  ( fun ... , (* body of m1 *)
  ...
  fun ... , (* body of mn *)
  )
```

} Tuple  
containing  
closures

- make ( ) is like the constructor
- The closure environment contains the fields

CMSC 330

5

## Relating Closures to Objects

```
let add1 x = x + 1
```

```
interface IntIntFun {
  Integer eval(Integer x);
}
class Add1 implements IntIntFun {
  Integer eval(Integer x) {
    return x + 1;
  }
}
```

```
add1 2;;
add1 3;;
```

```
new Add1().eval(2);
new Add1().eval(3);
```

CMSC 330

6

## Relating Closures to Objects

```
let app_to_1 f = f 1
```

```
interface IntIntFunFun {
  Integer eval(IntIntFun x);
}
class AppToOne
implements IntIntFunFun {
  Integer eval(IntIntFun f) {
    return f.eval(1);
  }
}
```

```
app_to_1 add1;;      new AppToOne().eval(new Add1());
```

CMSC 330

7

## Relating Closures to Objects

```
interface Func<T,U> {
  U eval(T x);
}
class AppToOne
implements Func<Func<Integer,Integer>,Integer> {
  Integer eval(Func<Integer,Integer> f) {
    return f.eval(1);
  }
}
```

```
app_to_1 add1;;      new AppToOne().eval(new Add1());
```

CMSC 330

8

## Relating Closures to Objects

```
let add a b = a + b;;
```

```
fun b -> a + b
```

```
let add1 = add 1;;
add1 4;;
```

```
class Add
  implements Func<Int,Func<Int,Int>> {
  private static class AddClosure
  implements Func<Int,Int> {
  private final Int a;
  AddClosure(Int a) {
  this.a = a;
  }
  Integer eval(Int b) {
  return a + b;
  }
  }
  Func<Int,Int> eval(Int x) {
  return new AddClosure(x);
  }
  }
```

```
Func<Int,Int> add1 = new Add().eval(1);
add1.eval(4);
```

## Encoding Closures with Objects

- ▶ We can apply this transformation in general

```
...(fun x -> (* body of fn *)) ...
let h f ... = ...f y...
```

- becomes

```
interface F<T,U> { U eval(T x); }
class G implements F<T,U> {
  U eval(T x) { /* body of fn */ }
}
class C {
  Typ1 h(F<Typ2,Typ3> f, ...) {
  ...f.eval(y)...
  }
}
```

- F is the interface to the callback
- G represents the particular function

## Code as Data

- ▶ Closures and objects are related
  - Both of them allow
    - Data to be associated with higher-order code
    - Pass code around the program
- ▶ The key insight in all of these examples
  - Treat code as if it were data
    - Allowing code to be passed around the program
    - And invoked where it is needed (as callback)
- ▶ Approach depends on programming language
  - Higher-order functions (OCaml, Ruby, Lisp)
  - Function pointers (C, C++)
  - Objects with known methods (Java)

## Code as Data (cont.)

- ▶ This is a powerful programming technique
  - Solves a number of problems quite elegantly
    - Create new control structures (e.g., Ruby iterators)
    - Add operations to data structures (e.g., visitor pattern)
    - Event-driven programming (e.g., observer pattern)
  - Keeps code separate
    - Clean division between higher & lower-level code
  - Promotes code reuse
    - Lower-level code supports different callbacks

## An Integer List Abstraction in Java

```
public class MyList {
    private class ConsNode {
        int head; MyList tail;
        ConsNode (int h, MyList l) { head = h; tail = l; }
    }
    private ConsNode contents;
    public MyList () {
        contents = null;
    }
    public MyList (int h, MyList l) {
        contents = new ConsNode (h, l);
    }
    public MyList cons (int h) {
        return (new MyList (h, this));
    }
    public int hd () {
        return contents.head;
    }
    public MyList tl () {
        return contents.tail;
    }
    public boolean isNull () {
        return (contents == null);
    }
}
```

CMSC 330

13

## Recall a Useful Higher-Order Function

```
let rec map f = function
  [] -> []
| (h::t) -> (f h)::(map f t)
```

- ▶ Map applies an arbitrary function **f**
  - To each element of a list
  - And returns the resulting modified list
- ▶ Can we encode this in Java?
  - Using object oriented programming

CMSC 330

14

## A Map Method for Lists in Java

- ▶ Problem – Write a map method in Java
  - Must pass a function into another function
- ▶ Solution
  - Can be done using an object with a **known** method
  - Use **interface** to specify what method must be present

```
public interface IntFunction {
    int eval(int arg);
}
```

CMSC 330

15

## A Map Method for Lists (cont.)

- ▶ Examples
  - Two classes which both implement **Function** interface

```
class AddOne implements IntFunction {
    int eval (int arg) {
        return (arg + 1);
    }
}
```

```
class MultTwo implements IntFunction {
    int eval(int arg) {
        return (arg * 2);
    }
}
```

CMSC 330

16

## The New List Class

```
class MyList {
  ...
  public MyList map (IntFunction f) {
    if (this.isNull()) return this;
    else return (this.tl()).map(f).cons (f.eval (this.hd()));
  }
}
```

CMSC 330

17

## Applying Map To Lists

- ▶ Then to apply the function, we just do

```
MyList l = ...;
MyList l1 = l.map(new AddOne());
MyList l2 = l.map(new MultTwo());
```

- We make a new object
  - > That has a method that performs the function we want
- This is sometimes called a **callback**
  - > Because `map` “calls back” to the object passed into it
- But it’s really just a higher-order function
  - > Written more awkwardly

CMSC 330

18

## We Can Do This for Fold Also!

- ▶ Recall fold

```
let rec fold f a = function
  [] -> a
  | (h::t) -> fold f (f a h) t
```

- Fold accumulates a value (in `a`) as it traverses a list
  - `f` is used to determine how to “fold” the head of a list into `a`
- ▶ This can be done in Java using an approach similar to `map`!

CMSC 330

19

## A Fold Method for Lists in Java

- ▶ Problem – Write a fold method in Java
  - Must pass a function into another function
- ▶ Solution
  - Can be done using an object with a **known** method
  - Use **interface** to specify what method must be present

```
public interface IntBinFunction {
  Integer eval(Integer arg1, Integer arg2);
}
```

CMSC 330

20

## A Fold Method for Lists (cont.)

### ▶ Examples

- A classes which implements `IntBinFunction` interface

```
class Sum implements IntBinFunction {
    Integer eval(Integer arg1, Integer arg2) {
        return new Integer(arg1 + arg2);
    }
}
```

### ▶ Note: this is not curried

- How might you make it so?

## The New List Class

```
class MyList {
    ...
    public MyList map (IntFunction f) {
        if (this.isNull()) return this;
        else return (this.tl()).map(f).cons (f.eval (this.hd()));
    }

    public int fold (IntBinFunction f, int a) {
        if (this.isNull()) return a;
        else return (this.tl()).fold(f, f.eval(a, this.hd()));
    }
}
```

## Applying Fold to Lists

### ▶ To apply the fold function, we just do this:

```
MyList l = ...;
int s = l.fold (new Sum(), 0);
```

### ▶ The result is that s contains the sum of the elements in l

## Java 8 eases the syntax

### ▶ Java 8 allows you to make objects that act as functions, more easily

- Instead of this

```
MyList l = ...;
MyList l1 = l.map(new AddOne());
MyList l2 = l.map(new MultTwo());
```

- Write this

```
MyList l = ...;
MyList l1 = l.map((x) -> x + 1);
MyList l2 = l.map((y) -> y * 2);
```
