BUT WHY MUST I BE SO STUPID?! The only reason I stayed is because it this class has I clickers,guess what I forgot to bring to class today?

12:18 PM - 15 Mar 2013

I have my clicker

A. True
B. False

Introduction

- Ruby is an *object-oriented, imperative, dynamically typed (scripting) language*

  - "I wanted a scripting language that was more powerful than Perl, and more object-oriented than Python. That's why I decided to design my own language."

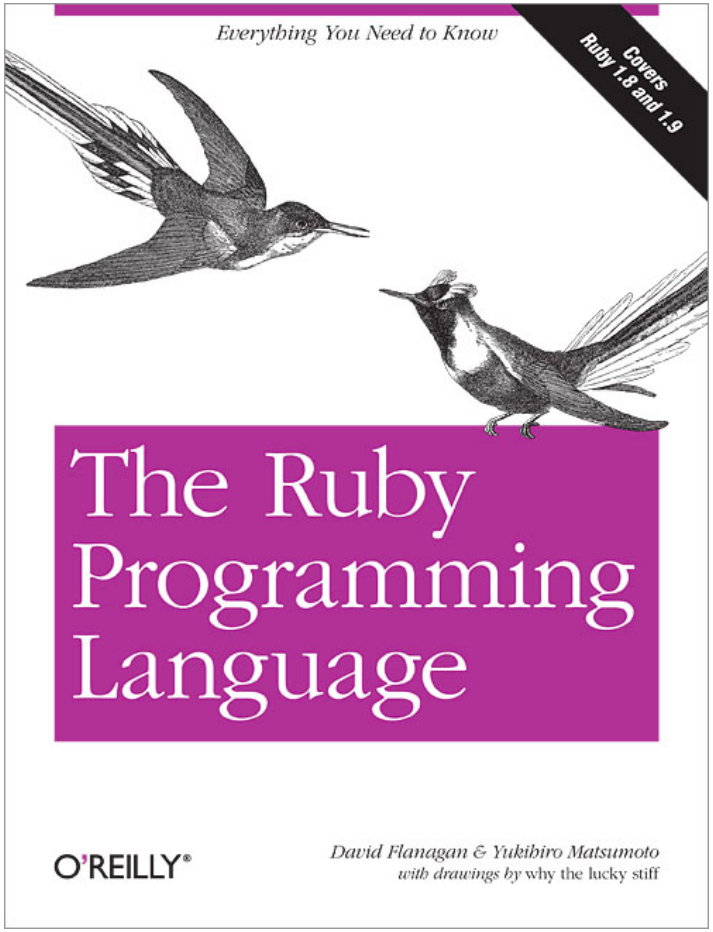
  - "I believe people want to express themselves when they program. They don't want to fight with the language. Programming languages must feel natural to programmers. I tried to make people enjoy programming and concentrate on the fun and creative part of programming when they use Ruby."

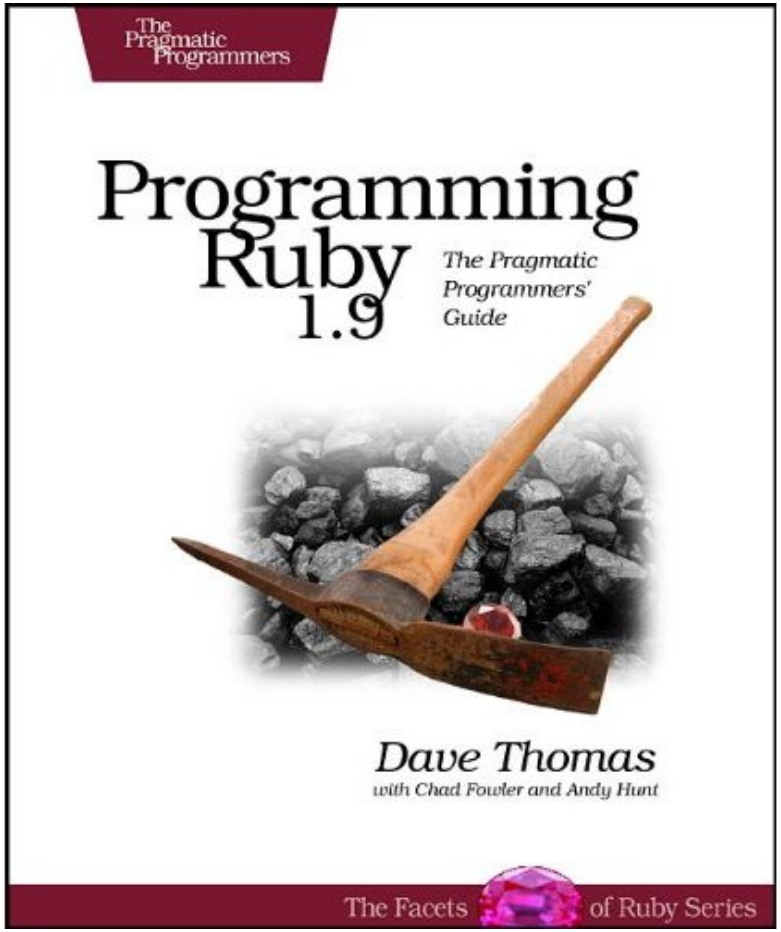
    – Yukihiro Matsumoto ("Matz")

Ruby

- An object-oriented, imperative, dynamically typed scripting language
  - Created in 1993 by Yukihiro Matsumoto (Matz)
  - "Ruby is designed to make programmers happy"
  - Core of Ruby on Rails web programming framework (a key to its popularity)
  - Similar in flavor to many other scripting languages
    - Much cleaner than perl
  - Full object-orientation (even primitives are objects!)

Books on Ruby





- Earlier version of Thomas book available on web
  - See course web page

Applications of Scripting Languages

- Scripting languages have many uses
  - Automating system administration
  - Automating user tasks
  - Quick-and-dirty development

- Motivating application

```

A Simple Example

- Let's start with a simple Ruby program

ruby1.rb:

```
# This is a ruby program
x = 37
y = x + 5
print(y)
print("\n")
```

```
% ruby -w ruby1.rb
42
%
```

Language Basics

comments begin with #, go to end of line

variables need not be declared

```
# This is a ruby program
x = 37
y = x + 5
print(y)
print("\n")
```

line break separates expressions (can also use ";" to be safe)

no special main() function or method

Run Ruby, Run

There are two basic ways to run a Ruby program

- ruby -w *filename* – execute script in *filename*
  - tip: the -w will cause Ruby to print a bit more if something bad happens
  - Ruby filenames should end with '.rb' extension
- irb – launch interactive Ruby shell
  - Can type in Ruby programs one line at a time, and watch as each line is executed

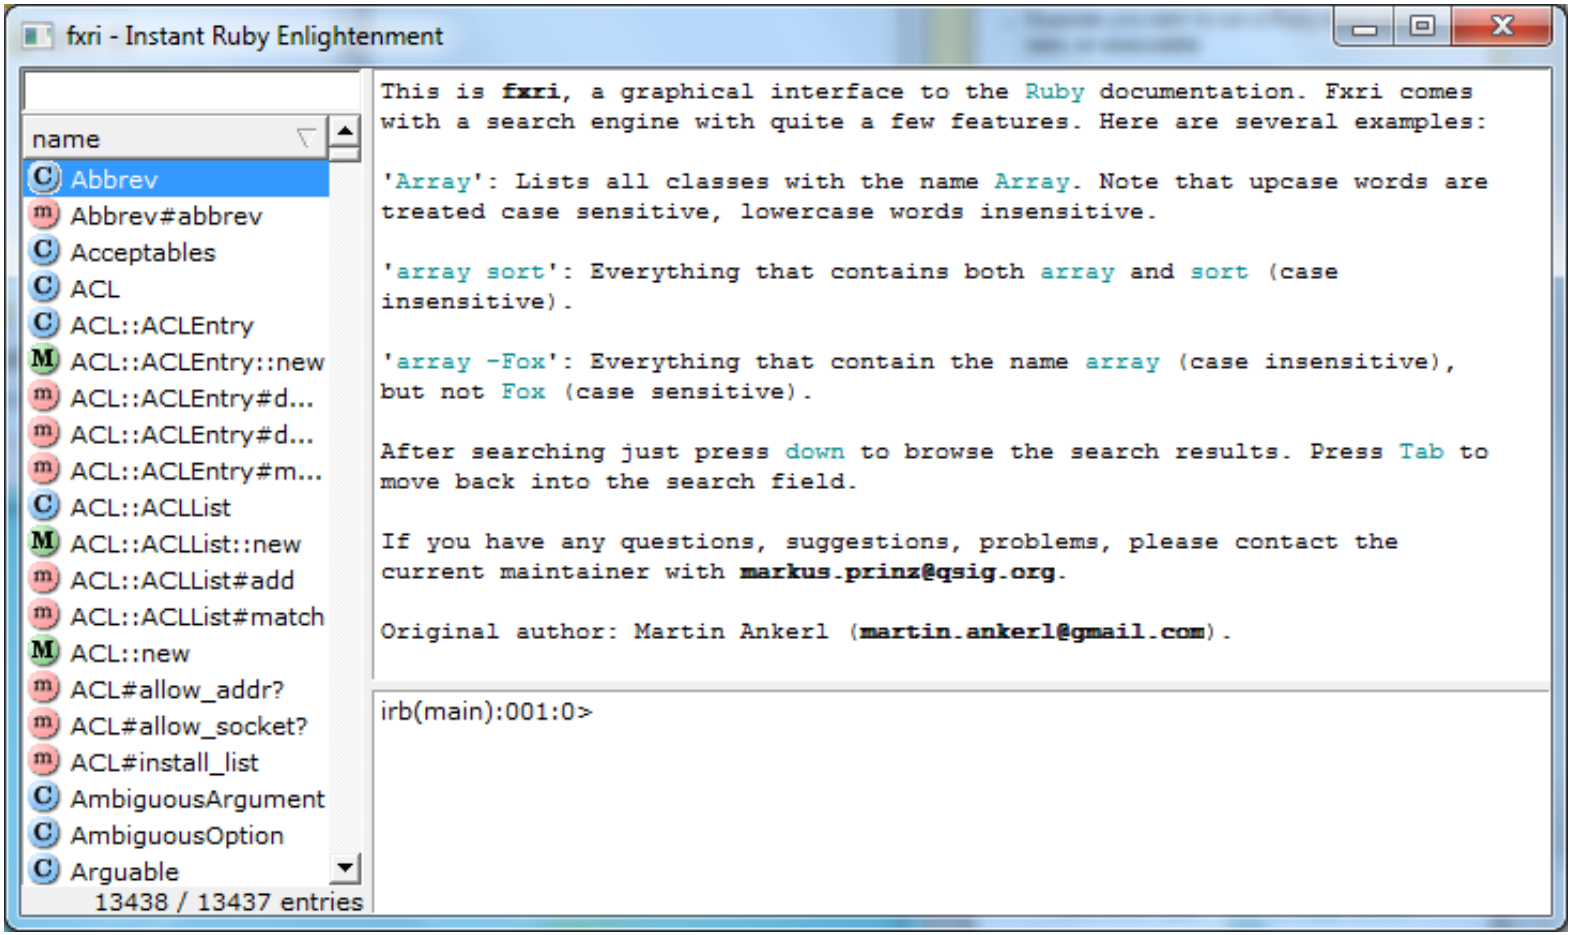
    irb(main):001:0> 3+4

    ⇒7
  - Can load Ruby programs via load command
    - Form: load *string*
    - String must be name of file containing Ruby program
    - E.g.: load 'foo.rb'

▸Ruby 1.9.3 is installed on Grace cluster (upgrading to 2.4)

Run Ruby, Run (cont.)

- fxri – launch standalone interactive Ruby shell



Run Ruby, Run (cont.)

- Suppose you want to run a Ruby script as if it were an executable (e.g. “double-click”, or as a command)
  - Windows
    - Must associate .rb file extension with ruby command
    - If you installed Ruby using the Windows installer, this was done automatically
    - The Ruby web site has information on how to make this association

Run Ruby, Run (cont.)

- Suppose you want to run a Ruby script as if it were an executable (cont.)
  - *nix (Linux / Unix / etc.)

```
#!/usr/local/bin/ruby -w
print("Hello, world!\n")
```

    - The first line ("shebang") tells the system where to find the program to interpret this text file
    - Must chmod u+x *filename* first, or chmod a+x *filename* so everyone has exec permission
    - Warning: Not very portable: Depends on location of Ruby interpreter
      - /usr/local/bin/ruby vs. /usr/bin/ruby vs. /opt/local/bin/ruby etc.

Creating Ruby Programs

- As with most programming languages, Ruby programs are text files.
  - Note: there are actually different versions of "plain text"! E.g. ASCII, Unicode, Utf-8, etc.
  - You won't need to worry about this in this course.
- To create a Ruby program, you can use your favorite text editor, e.g.
  - notepad++ (free, much better than notepad)
  - emacs (free, infinitely configurable)
  - vim
  - Eclipse (see web page for plugin instructions)
  - Many others

Some Ruby Language Features

- Implicit declarations
  - Java, C have explicit declarations
- Dynamic typing
  - Java, C have (mostly) static typing
- Everything is an object
  - No distinction between objects and primitive data
  - Even “null” is an object (called *nil* in Ruby), as are classes
- No outside access to private object state
  - *Must* use getters, setters
- No method overloading
- Class-based and Mixin inheritance

Implicit vs. Explicit Declarations

- In Ruby, variables are implicitly declared
  - First use of a variable declares it and determines type

```
x = 37;  // no declaration needed – created when assigned to
y = x + 5
```

    - x, y now exist, are integers

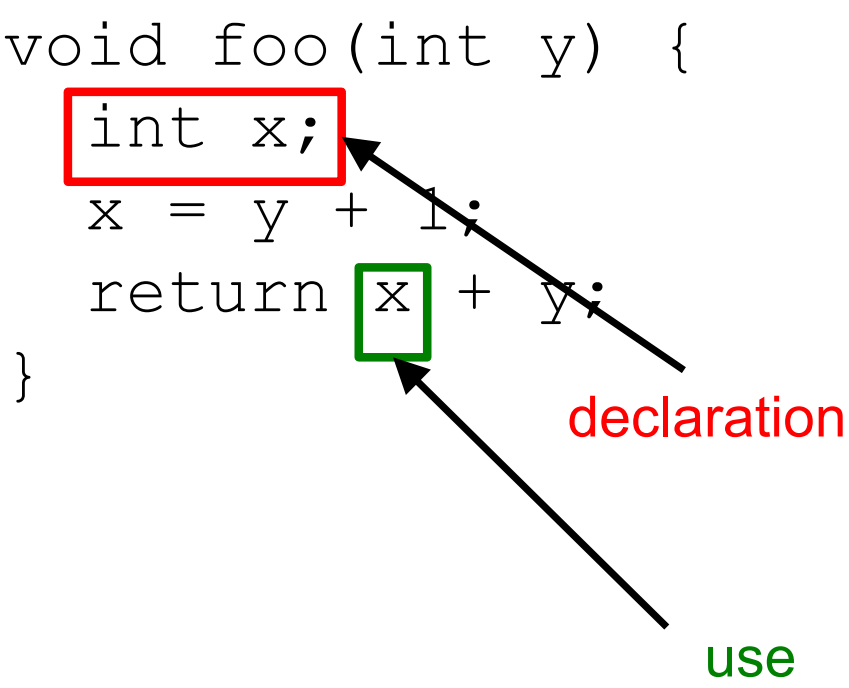
- Java and C/C++ use explicit variable declarations
  - Variables are named and typed before they are used

```
int x, y;   // declaration
x = 37;   // use
y = x + 5;  // use
```

Implicit vs. Explicit Declarations

- Explicit declarations identify allowed names
  - Variables must be declared before used

C, Java, C++, etc.

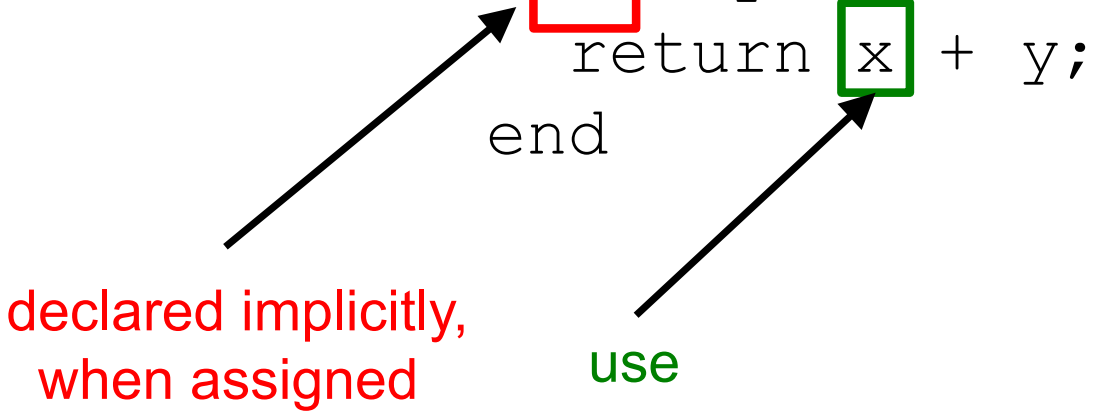


Implicit vs. Explicit Declarations

- Allowed names also declared implicitly
  - Variables do not need to be declared
    - Implicit declaration when first assigned to

Ruby

```
def foo(y)
  x = y + 1;
  return x + y;
end
```



Also: Perl, Python

Tradeoffs?

Explicit Declarations	Implicit Declarations
More text to type	Less text to type
Helps prevent typos	Easy to mistype variable name

```
var = 37
If (rare-condition)
  y = vsr + 5
```

Typo!

Only caught when this line is actually run.

Bug could be latent for quite a while

Static Type Checking (Static Typing)

- Before program is run
  - Types of all expressions are determined
  - Disallowed operations cause compile-time error
    - Cannot run the program

- Static types are often explicit (*aka* manifest)
  - Specified in text (at variable declaration)
    - C, C++, Java, C#
  - But may also be inferred – compiler determines type based on usage
    - OCaml, C# and Go (limited)

Dynamic Type Checking

- During program execution
  - Can determine type from run-time value
  - Type is checked before use
  - Disallowed operations cause run-time exception
    - Type errors may be latent in code for a long time
- Dynamic types are *not* manifest (aka implicit)
  - Variables are just introduced/used without types
  - Examples
    - **Ruby**, Python, Javascript, Lisp

Static and Dynamic Typing

- Ruby is dynamically typed, C is statically typed

```
# Ruby
x = 3
x = "foo"   # gives x a
            # new type
x.foo       # NoMethodError
            # at runtime
```

```
/* C */
int x;
x = 3;
x = "foo"; /* not allowed */
/* program doesn't compile */
```

- Notes
  - Can always run the Ruby program; may fail when run
  - C variables declared, with types
    - Ruby variables declared *implicitly*
    - Implicit declarations most natural with dynamic typing

Tradeoffs?

- Static type checking
  - More work for programmer (at first)
    - Catches more (and subtle) errors at compile time
  - Precludes some correct programs
    - May require a contorted rewrite
  - More efficient code (fewer run-time checks)
- Dynamic type checking
  - Less work for programmer (at first)
    - Delays some errors to run time
  - Allows more programs
    - Including ones that will fail
  - Less efficient code (more run-time checks)

Java: *Mostly* Static Typing

- In Java, types are mostly checked statically

```
Object x = new Object();
x.println("hello");   // No such method error at compile time
```

- But sometimes checks occur at run-time

```
Object o = new Object();
String s = (String) o;  // No compiler warning, fails at run time
// (Some Java compilers may be smart enough to warn about
   above cast)
```

Control Statements in Ruby

- A control statement is one that affects which instruction is executed next
  - While loops
  - Conditionals

```
i = 0
while i < n
  i = i + 1
end
```

```
if grade >= 90 then
  puts "You got an A"
elsif grade >= 80 then
  puts "You got a B"
elsif grade >= 70 then
  puts "You got a C"
else
  puts "You're not doing so well"
end
```

Conditionals and Loops Must End!

- All Ruby conditional and looping statements must be terminated with the end keyword.
- Examples

```
if grade >= 90 then
  puts "You got an A"
end
```

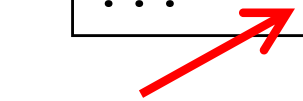
```
if grade >= 90 then
  puts "You got an A"
else
  puts “No A, sorry"
end
```

```
i = 0
while i < n
  i = i + 1
end
```

What is True?

- The guard of a conditional is the expression that determines which branch is taken

```
if grade >= 90 then
...
```



Guard

- The true branch is taken if the guard evaluates to anything except
  - false
  - nil
- Warning to C programmers: **0 is not false!**

Yet More Control Statements in Ruby

- unless cond then stmt-f else stmt-t end
  - Same as "if not cond then stmt-t else stmt-f end"

```
unless grade < 90 then
  puts "You got an A"
else unless grade < 80 then
  puts "You got a B"
end
```

- until cond body end
  - Same as "while not cond body end"

```
until i >= n
  puts message
  i = i + 1
end
```

Using If and Unless as Modifiers

- Can write if and unless after an expression
  - puts "You got an A" if grade >= 90
  - puts "You got an A" unless grade < 90

- Why so many control statements?
  - Is this a good idea? Why or why not?
    - **Good**: can make program more readable, expressing programs more directly. In natural language, many ways to say the same thing, which supports brevity and adds style.
    - **Bad**: many ways to do the same thing may lead to confusion and hurt maintainability (if future programmers don't understand all styles)

Other Useful Control Statements

```
for elt in [1, "math", 3.4]
   puts elt.to_s
end
```

generates a string; cf. to_i

```
for i in (1..3)
   puts i
end
```

```
while i>n
   break
   next
   puts message
   redo
end
```

```
(1..3).each {
   |elt|
   puts elt
}
```

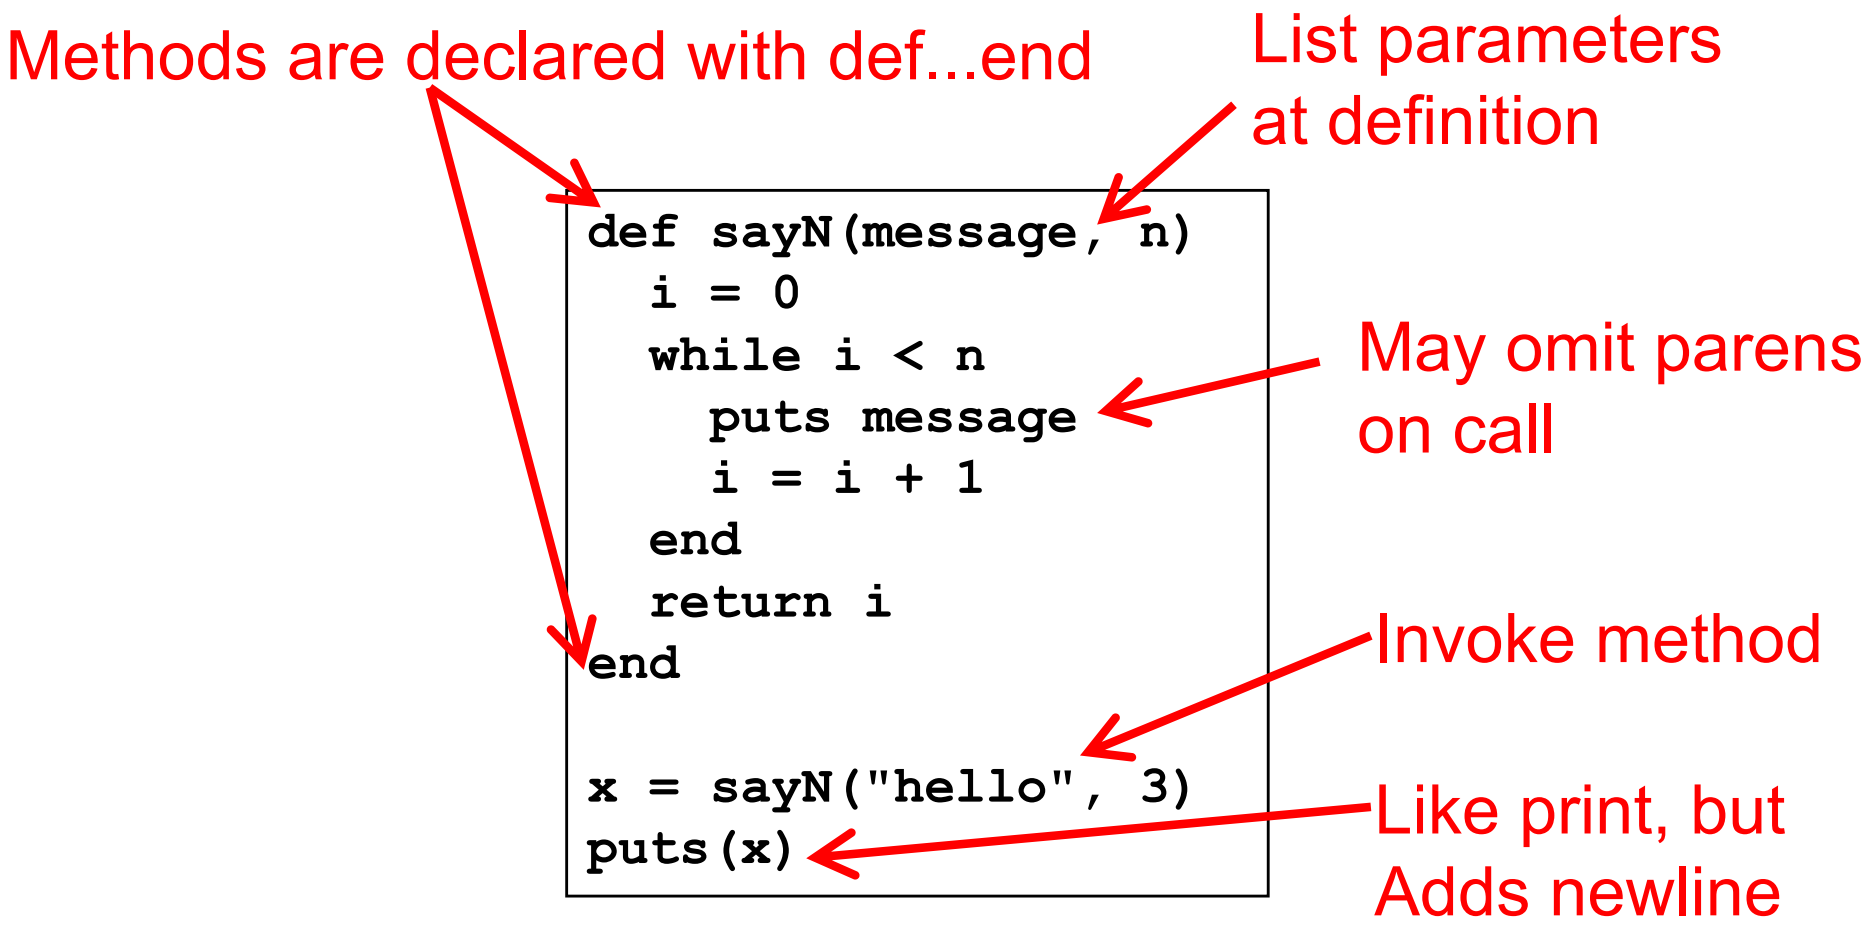
```
IO.foreach(filename)
{ |x|
   puts x
}
```

code block (details later)

```
case x
when 1, 3..5
when 2, 6..8
end
```

does not need break

Methods in Ruby



Methods should begin with lowercase letter and be defined before they are called
Variable names that begin with uppercase letter are *constants* (only assigned once)

Terminology

- Formal parameters
  - Variable parameters used in the method
  - def sayN(message, n) in our example
- Actual arguments
  - Values passed in to the method at a call
  - x = sayN("hello", 3) in our example
- Top-level methods are “global”
  - Not part of a class. sayN is a top-level method.

Method Return Values

- Value of the return is the value of the last executed statement in the method
  - These are the same:

```
def add_three(x)
  return x+3
end
```

```
def add_three(x)
  x+3
end
```

- Methods can return multiple results (as a list)

```
def dup(x)
  return x,x
end
```

Everything is an Object

- All values are (references to) objects
  - Java/C/C++ distinguish *primitives* from *objects*
- Objects communicate via method calls
- Each object has its own (private) state
- Every object is an instance of a class
  - An object's class determines its behavior:
  - The class contains method and field definitions
    - Both instance fields and per-class ("static") fields

Everything is an Object

- Examples
  - (-4).abs ← No-argument instance method of Fixnum
    - integers are instances of class Fixnum
  - 3 + 4
    - infix notation for "invoke the + method of 3 on argument 4"
  - "programming".length
    - strings are instances of String
  - String.new
    - classes are objects with a new method
  - 4.13.class
    - use the class method to get the class for an object
    - floating point numbers are instances of Float

Classes

- Class names begin with an uppercase letter
- The new method creates an object
  - s = String.new creates a new String and makes s refer to it
- Every class inherits from Object

Objects and Classes

- Objects are data
- Classes are types (the kind of data which things are)
- Classes are *also* objects

Object	Class (aka *type*)
10	Fixnum
-3.30	Float
"CMSC 330"	String
String.new	String
[‘a’, ‘b’, ‘c’]	Array
Fixnum	Class

- Fixnum, Float, and String are *objects* of type Class
  - So is Class itself!

Two Cool Things to Do with Classes

- Since classes are objects, you can manipulate them however you like
  - Here, the type of y depends on p
    - Either a String or a Time object

```
if p then
  x = String
else
  x = Time
End
y = x.new
```

- You can get names of all the methods of a class
  - Object.methods
    - => ["send", "name", "class_eval", "object_id", "new", "autoload?", "singleton_methods", ...]

The nil Object

- Ruby uses a special object nil
  - All uninitialized fields set to nil (@ prefix used for fields)

    ```
    irb(main):004:0> @x
    => nil
    ```

  - Like NULL or 0 in C/C++ and null in Java
- nil is an object of class NilClass
  - It's a *singleton object* – there is only one instance of it
    - NilClass does not have a **new** method
  - nil has methods like to_s, but not other methods

    ```
    irb(main):006:0> nil + 2
    NoMethodError: undefined method `+' for nil:NilClass
    ```

Creating Strings in Ruby

- Substitution in double-quoted strings with #{ }
  - course = "330"; msg = "Welcome to #{course}"
  - "It is now #{Time.new}"
  - The contents of #{ } may be an arbitrary expression
  - Can also use single-quote as delimiter
    - No expression substitution, fewer escaping characters
- Here-documents

```
s = <<END
  This is a text message on multiple lines
  and typing \\n is annoying
END
```

Creating Strings in Ruby (cont.)

- Ruby has printf and sprintf
  - printf("Hello, %s\n", name);
  - sprintf("%d: %s", count, Time.now)
    - Returns a String
- to_s returns a String representation of an object
  - Can be invoked implicitly – write puts(p) instead of puts(p.to_s)
    - Like Java's toString()
- inspect converts any object to a string

```
irb(main):033:0> p.inspect
=> "#<Point:0x54574 @y=4, @x=7>"
```

Standard Library: String

- The String class has many useful methods
  - s.length # length of string
  - s1 == s2 # structural equality (string contents)
  - s = "A line\n"; s.chomp # returns "A line"
    - Return new string with s's contents except newline at end of line removed
  - s = "A line\n"; s.chomp!
    - Destructively removes newline from s
    - *Convention:* methods ending in ! modify the object
    - *Another convention:* methods ending in ? observe the object

Method naming style

- Names of methods that return a boolean should end in ?
- Names of methods that modify an object's state should end in !
- Example: suppose x = [3,1,2] (this is an array)
  - x.member? 3 returns true since 3 is in the array x
  - x.sort returns a new array that is sorted
  - x.sort! modifies x in place

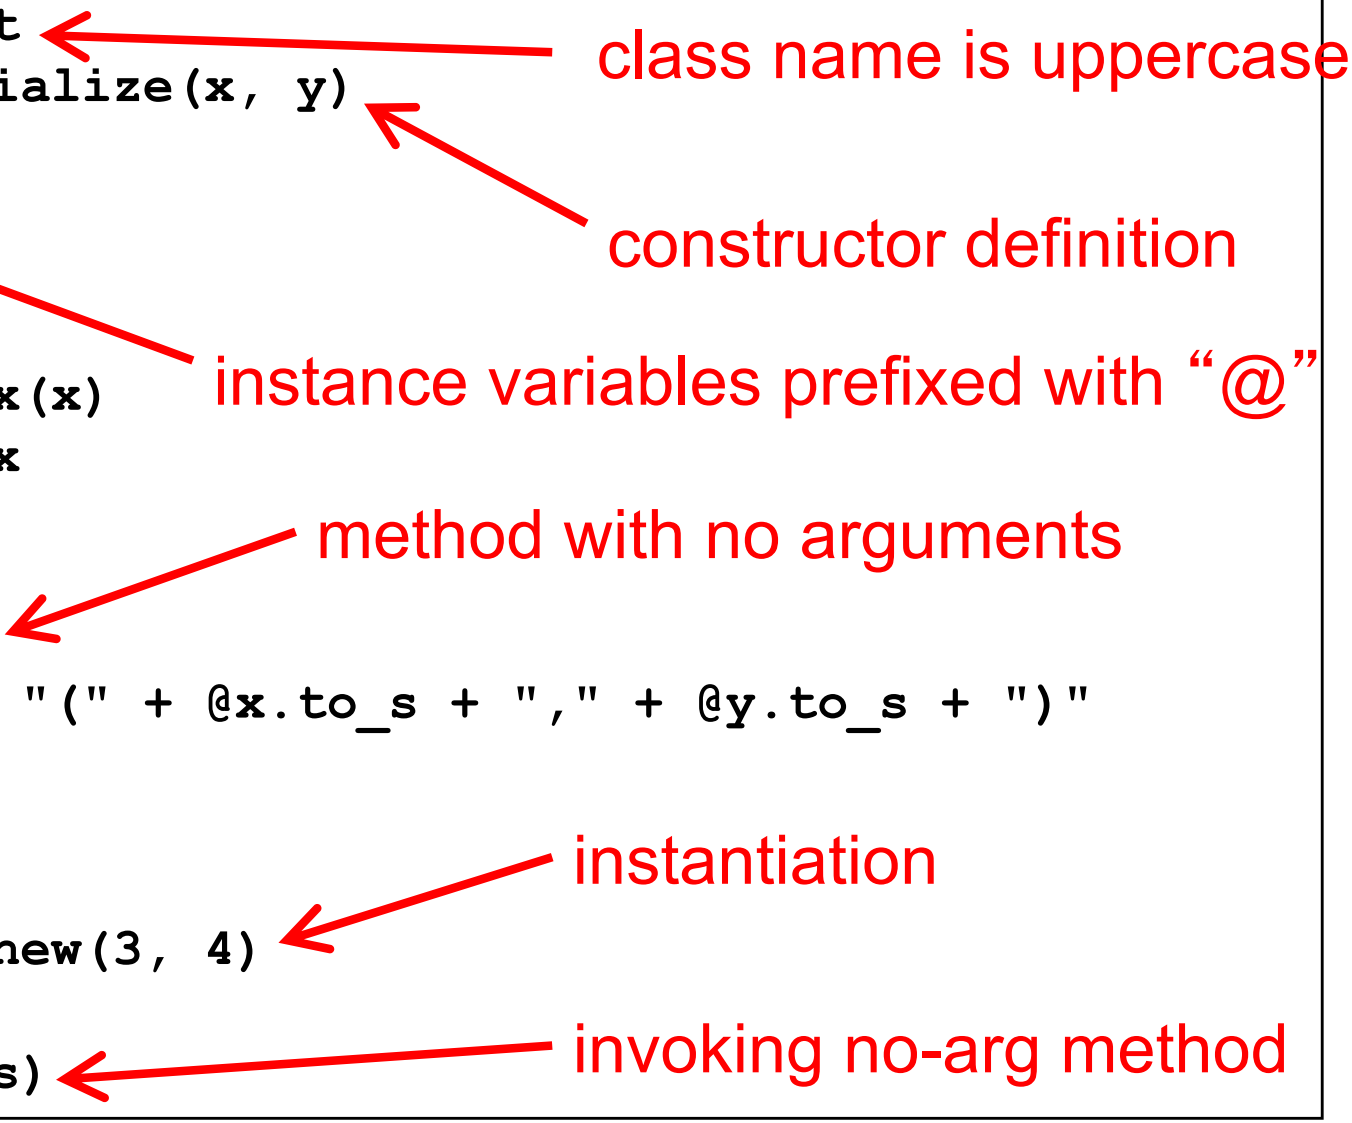
Defining Your Own Classes

```
class Point
  def initialize(x, y)
    @x = x
    @y = y
  end

  def add_x(x)
    @x += x
  end

  def to_s
    return "(" + @x.to_s + "," + @y.to_s + ")"
  end
end

p = Point.new(3, 4)
p.add_x(4)
puts(p.to_s)
```



No Outside Access To Internal State

- Instance variables (with @) can be directly accessed only by instance methods
- Outside class, they require accessors:

A typical getter

```
def x
  @x
end
```

A typical setter

```
def x= (value)
  @x = value
end
```

- Very common, so Ruby provides a shortcut

```
class ClassWithXandY
  attr_accessor “x”, “y”
end
```

Says to generate the x= and x and y= and y methods

No Method Overloading in Ruby

- Thus there can only be one initialize method
  - A typical Java class might have two or more constructors
- No overloading of methods in general
  - You can code up your own overloading by using a variable number of arguments, and checking at run-time the number/types of arguments
- Ruby does issue an exception or warning if a class defines more than one initialize method
  - But last initialize method defined is the valid one

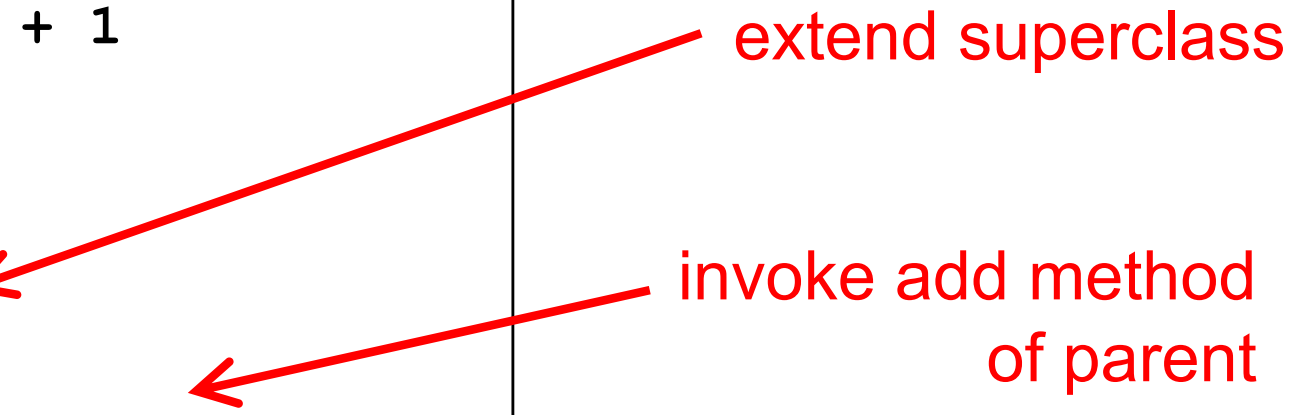
Inheritance

- Recall that every class inherits from Object

```
class A          ## < Object
  def add(x)
    return x + 1
  end
end

class B < A
  def add(y)
    return (super(y) + 1)
  end
end

b = B.new
puts(b.add(3))
```



```
b.is_a? A
true
b.instance_of? A
false
```

Mixins

- Another form of code reuse is "mix-in" inclusion
  - `include A` "inlines" A's methods at that point
    - Referred-to variables/methods captured from context
    - In effect: it adds those methods to the current class

```
class OneDPoint
  attr_accessor "x"
  include Comparable
  def <=>(other)# used by Comparable
    if @x < other.x then return -1
    elsif @x > other.x then return 1
    else return 0
    end
  end
end
```

```
p = OneDPoint.new
p.x = 1
q = OneDPoint.new
q.x = 2
x < y # true
puts [y,x].sort
# prints x, then y
```

super( ) in Ruby

- Within the body of a method
  - Call to super( ) acts just like a call to that original method
  - Except that search for method body starts in the superclass of the object that was found to contain the original method

Global Variables in Ruby

- Ruby has two kinds of global variables
  - Class variables beginning with @@ (`static` in Java)
  - Global variables across classes beginning with $

```
class Global
  @@x = 0

  def Global.inc
    @@x = @@x + 1; $x = $x + 1
  end

  def Global.get
    return @@x
  end
end
```

```
$x = 0
Global.inc
$x = $x + 1
Global.inc
puts(Global.get)
puts($x)
```

define a class ("singleton") method

Special Global Variables

- Ruby has a special set of global variables that are implicitly set by methods
- The most insidious one: $_
  - Last line of input read by gets or readline
- Example program

```
gets     # implicitly reads input line into $_
print    # implicitly prints out $_
```

- Using $_ leads to shorter programs
  - And confusion
  - We suggest you avoid using it

What is a Program?

- In C/C++, a program is...
  - A collection of declarations and definitions
  - With a distinguished function definition
    - int main(int argc, char *argv[]) { ... }
  - When you run a C/C++ program, it's like the OS calls main(...)
- In Java, a program is...
  - A collection of class definitions
  - With some class (say, MyClass) containing a method
    - public static void main(String[] args)
  - When you run java MyClass, the main method of class MyClass is invoked

A Ruby Program is...

- The class Object
  - When the class is loaded, any expressions not in method bodies are executed

defines a method of Object
(i.e., top-level methods belong to Object)

invokes self.sayN

invokes self.puts
(part of Object)

```
def sayN(message, n)
  i = 0
  while i < n
    puts message
    i = i + 1
  end
  return i
end

x = sayN("hello", 3)
puts(x)
```

Summary

- Scripting languages
- Ruby language
  - Implicit variable declarations
  - Dynamic typing
  - Many control statements
  - Classes & objects
  - Strings
