

# CMSC330 Fall 2013 Final Exam Solutions

1. (20 pts) Programming languages
  - a. (4 pts) Explain why programming languages use types (e.g., int x, char y).  
**To specify valid operations for a group of values, and catch errors when the value is used inappropriately.**
  - b. (4 pts) Explain why static types do not ensure a strong type system.  
**Because the language may allow many implicit casts (e.g., C), or operations that are not type safe (e.g., printf(%d,1.0)).**
  - c. (4 pts) Explain why programming languages use scopes (e.g., {...}, begin ... end).  
**To limit the lifetime of a variable name (binding), so the name may be reused. Scopes also specify which variable a name refers to when shadowing.**
  - d. (4 pts) Explain when programming languages need to use closures.  
**When functions are used as return values (upwards funargs), and the returned function  $F$  can access variables in an enclosing scope from a function that will have already returned by the time  $F$  is called.**
  - e. (4 pts) Explain why closures are similar to objects.  
**Closures contain both code (methods) and an environment (data), and may be used to implement objects.**
2. (16 pts) Ruby & OCaml

What is the output (if any) of the following Ruby programs? Write FAIL if code does not execute.

  - a. (2 pts) 

```
a = "Captain America"
if a =~ /[a-z]+/ then
  puts $1
end
```

**# Output = captain**
  - b. (2 pts) 

```
a = {}
a["Iron"] = "Man"
puts a["Iron"]
```

**# Output = Man**
  - c. (4 pts) Give the type of the following OCaml expression  

```
fun x -> fun y -> y::x
```

**Type = 'a list -> 'a -> 'a list**
  - d. (4 pts) Write an OCaml expression with the following type  

```
('a -> 'a list) -> int list
```

**Code = fun x -> (fun y -> y::(x y)) ; [1]**
  - e. (4 pts) Give the value of the following OCaml expression. If an error exists, describe the error.  

```
fold (fun x -> fun y -> y::x) [ ] [2;3;4]
```

**Value = [4;3;2]**

3. (9 pts) Scoping

Consider the following OCaml code.

```
let app f y = let x = 4 in (f y)+1 ;;
let proc x = let change z = z-x in app change (x+3) ;;
(proc 2) ;;
```

**Value computed by change z is z-x. With static scoping, x = 1<sup>st</sup> argument for proc. With dynamic scoping, x is redefinition of x=4 in app.**

a. (3 pts) What value is returned by (proc 2) with static scoping? Explain.

**4, since value of x in change is the formal parameter x in proc x (i.e., 2).  
(proc x:2) -> app change (2+3=5) -> (change 5)+1 -> (5-2)+1 = 4**

b. (6 pts) What value is returned by (proc 2) with dynamic scoping? Explain.

**2, since value of x in change is 4, the redefinition of x=4 in app.  
(proc x:2) -> app change (2+3=5) -> (change 5)+1 -> (5-4)+1 = 2**

4. (12 pts) Parameter passing

Consider the following C code.

```
int i = 2;
void foo(int f, int g) {
    f = f + g;
    g = g + 4;
}
int main() {
    int a[] = {1, 1, 1, 1};
    foo(i, a[i-2]);
    printf("%d %d %d %d %d\n", i, a[0], a[1], a[2], a[3]);
}
```

a. (2 pts) Give the output if C uses call-by-value

**2 1 1 1 1 // since i & a[0] are unchanged by calling foo**

b. (5 pts) Give the output if C uses call-by-reference

**3 5 1 1 1 // since i & a[0] are changed by calling foo  
// f = i, g = a[0] -> i = i+a[0] ; a[0] = a[0]+4**

c. (5 pts) Give the output if C uses call-by-name

**3 1 5 1 1 // since i and a[i-2] are changed by calling foo  
// f = i, g = a[i-2] -> i = i+a[i-2] ; a[i-2] = a[i-2]+4**

5. (10 pts) Lazy evaluation

Rewrite the following OCaml code using thunks so that foo uses lazy evaluation.

```
let foo x = x + 1;;  
foo (2+3);;
```

```
let foo x = x() + 1;;  
foo (fun () -> 2+3);;
```

6. (8 pts) Garbage collection

Consider the following Java code.

```
class AvengersMovie {  
    static Avenger x, y, z;  
    private void MoviePlot() {  
        x = new Avenger ("Iron Man");           // object 1  
        y = new Avenger ("Black Widow");       // object 2  
        z = new Avenger ("Bruce Banner");       // object 3  
        // transformation!  
        z = new Avenger("Hulk");                 // object 4  
    }  
}
```

a. (4 pts) What object(s) are garbage when MoviePlot ( ) returns? Explain.

**Object 3 (Bruce Banner), since it can no longer be accessed.**

b. (4 pts) List one advantage and one disadvantage of using garbage collection.

**Advantages = less programmer effort, fewer memory errors**

7. (12 pts) Polymorphism

- a. (4 pts) Explain why + in Java is an example of ad hoc polymorphism.

**+ works only for a small number of argument types (e.g., int, float, String) and performs different actions (e.g., sum, concat) depending on the type.**

- b. (4 pts) Briefly explain why Java generics is an example of parametric polymorphism.

**Java generics (e.g., HashMap<T>) allow a function/class to be applied to a range of different argument types.**

- c. (4 pts) Briefly explain why “?” is used for Java generics, such as Set<?>.

**Wildcards such as ? are needed to support subtyping for containers.**

8. (20 pts) Lambda calculus

- a. (4 pts)  $(\lambda x. \lambda y. y \ x \ y \ x) \ y \ x \ z$

$(\lambda x. \lambda y. y \ x \ y \ x) \ y \ x \ z \rightarrow (\lambda x. \lambda b. b \ x \ b \ x) \ y \ x \ z \rightarrow (\lambda b. b \ y \ b \ y) \ x \ z \rightarrow \mathbf{(x \ y \ x \ y) \ z}$

- b. (6 pts)  $(\lambda x. \lambda y. \lambda z. y \ z \ x) \ (\lambda c. c) \ (\lambda a. \lambda b. b \ a) \ d$

$(\lambda x. \lambda y. \lambda z. y \ z \ x) \ (\lambda c. c) \ (\lambda a. \lambda b. b \ a) \ d \rightarrow$

$(\lambda y. \lambda z. y \ z \ (\lambda c. c)) \ (\lambda a. \lambda b. b \ a) \ d \rightarrow$

$(\lambda z. (\lambda a. \lambda b. b \ a) \ z \ (\lambda c. c)) \ d \rightarrow$

**THEN ONE OF**

$(\lambda a. \lambda b. b \ a) \ d \ (\lambda c. c) \rightarrow (\lambda b. b \ d) \ (\lambda c. c) \rightarrow (\lambda c. c) \ d \rightarrow \mathbf{d}$

**OR**

$(\lambda z. (\lambda b. b \ z) \ (\lambda c. c)) \ d \rightarrow (\lambda b. b \ d) \ (\lambda c. c) \rightarrow (\lambda c. c) \ d \rightarrow \mathbf{d}$

**OR**

$(\lambda z. (\lambda b. b \ z) \ (\lambda c. c)) \ d \rightarrow (\lambda z. (\lambda c. c) \ z) \ d \rightarrow (\lambda z. z) \ d \rightarrow \mathbf{d}$

**OR**

$(\lambda z. (\lambda b. b \ z) \ (\lambda c. c)) \ d \rightarrow (\lambda z. (\lambda c. c) \ z) \ d \rightarrow (\lambda c. c) \ d \rightarrow \mathbf{d}$

Lambda calculus encodings

- c. (10 pts) Using encodings, show  $\text{succ } 3 \Rightarrow^* 4$ . Show each beta-reduction.

$\Rightarrow^*$  indicates 0 or more steps of beta-reduction

$(\lambda z. \lambda f. \lambda y. f \ (z \ f \ y)) \ 3 \rightarrow$

$\lambda f. \lambda y. f \ (3 \ f \ y) \rightarrow$

$\lambda f. \lambda y. f \ ((\lambda f. \lambda y. f \ (f \ (f \ y))) \ f \ y) \rightarrow$

$\lambda f. \lambda y. f \ ((\lambda y. f \ (f \ (f \ y))) \ y) \rightarrow$

$\lambda f. \lambda y. f \ (f \ (f \ y)) \rightarrow$

**4**

$\text{succ} = \lambda z. \lambda f. \lambda y. f \ (z \ f \ y)$

$0 = \lambda f. \lambda y. y$

$1 = \lambda f. \lambda y. f \ y$

$2 = \lambda f. \lambda y. f \ (f \ y)$

$3 = \lambda f. \lambda y. f \ (f \ (f \ y))$

$4 = \lambda f. \lambda y. f \ (f \ (f \ (f \ y)))$

9. (15 pts) Multithreading

<pre>class Buffer {   Buffer ( ) {     Object obj = Object.new     Object buf = null;     boolean empty = true;   } }</pre>	<pre>void produce(o) {   synchronize (obj) {     1. if (!empty) wait( );     2. empty = false;     3. notifyAll( );     4. buf = o;   } }</pre>	<pre>Object consume( ) {   synchronize (obj) {     5. if (empty) wait( );     6. empty = true;     7. notifyAll( );     8. return buf;   } }</pre>
---	---	--

Consider the multithreaded Java 1.4 code above. Assume there are multiple producer & consumer threads being executed in the program, but just a *single* Buffer object. If we freeze program execution at some point in time, each thread *T* will have just finished executing some statement *S* (i.e., statement *S* will have been the last statement executed by thread *T*). We wish to examine the state of these threads.

- a. (4 pts) Is it possible given two threads *x* and *y* for the last statement executed by thread *x* to be statement 2 and thread *y* to be statement 7 in the code above? Explain your answer.

**No, since if the last statement executed by a thread is either statement 2 or 7, it must be holding the lock. No other thread can acquire the lock and reach statement 2 or 7.**

- b. (5 pts) Is it possible given two threads *x* and *y* for the last statement executed by thread *x* to be statement 5 and thread *y* to be statement 3 in the code above? Explain your answer.

**Yes, since thread *x* may have reached statement 5 and released the lock after calling wait, so thread *y* may acquire the lock and reach & execute statement 3.**

- c. (6 pts) Is it possible in the code above for two threads calling consume( ) to get the same object *o* passed to produce(*o*)? Explain your answer.

**Yes, since the wait at line 5 is not called in a while loop. It is possible for a thread at line 5 to be woken and execute lines 6-8 even though empty is still true. This will cause the thread to return the buffer value already returned by a different consumer.**

10. (30 pts) Ruby multithreading

```
require "monitor"
```

```
def goTrain(me)
  10.times {
    r = getRoom()
    $locks[r].synchronize {
      if $rooms[r].empty?
        $rooms[r].push(me)
        $conds[r].wait_until { $rooms[r].empty? } # woken by partner
      else
        partner = $rooms[r].pop
        sleep 0.01 # train!
        puts "Room #{r} training #{me} & #{partner}"
        $conds[r].broadcast
      end
    }
  }
end
```

```
def simulate(m,n)
  $nHeroes = m;
  $nRooms = n;
  $rooms = []
  $locks = []
  $conds = []

  # prepare training rooms
  $nRooms.times { |i|
    $rooms[i] = []
    $locks[i] = Monitor.new
    $conds[i] = $locks[i].new_cond
  }

  # start hero training
  threads = []
  $nHeroes.times { |me|
    t = Thread.new { goTrain(me) }
    threads.push(t)
  }
  threads.each { |t| t.join }

end
```

11. (20 pts) Prolog

Given the following clauses, list all answers returned by the following queries.

<pre>avenger(ironman). avenger(thor). sibling(thor,loki). asgardian(thor). asgardian(X) :- sibling(Y,X),asgardian(Y). train1(X,Y) :- avenger(X),!,avenger(Y). train2(X,Y) :- avenger(X),X\=Y,avenger(Y).</pre> <p>a. (2 pts) ?- avenger(thor). <b>true.</b></p> <p>b. (2 pts) ?- asgardian(A). <b>A=thor;</b> <b>A=loki.</b></p> <p>c. (2 pts) ?- train1(A,B). <b>A=ironman,</b> <b>B=ironman;</b> <b>A=ironman,</b> <b>B=thor.</b></p> <p>d. (3 pts) ?- train2(A,thor). <b>A=ironman.</b></p> <p>e. (3 pts) ?- train2(thor,A). <b>false.</b></p>	<pre>foo([H,H T],H). foo([_ T],R) :- foo(T,R).</pre> <p>f. (2 pts) ?- foo([1,2],A). <b>false.</b></p> <p>g. (3 pts) ?- foo([2,2],A). <b>A=2.</b></p> <p>h. (3 pts) ?- foo([1,2,2,3,4,4],A) <b>A=2;</b> <b>A=4.</b></p>
---	--

12. (28 pts) Prolog programming

Write a prolog function `findDups(A,X,Y)` that given a list `A`, looks for adjacent duplicate values `X` starting at index `Y`, where the first element has index 0. If there are multiple duplicates, backtracking should return additional answers, starting from left to right in the list. `findDups()` fails if there are no duplicates in `A`. You may use the operators `=`, `\=`, `\+`, `is`, `+`, `-`, `[H|T]`, and `!`. You do not need to worry about efficiency.

Examples:

<code>?- findDups([],X,Y). false. ?- findDups([1],X,Y). false.</code>	<code>?- findDups([1,2],X,Y). false. ?- findDups([1,1],X,Y). X=1, Y=0.</code>	<code>?- findDups([0,1,1,2,2],X,Y). X=1, Y=1; X=2, Y=3.</code>
---	---	--

**`find([H,H|T],I,H,I).`**  
**`find(_|T,N,R,I) :- N1 is N+1, find(T,N1,R,I).`**  
**`findDup(L,X,Y) :- find(L,0,X,Y).`**
