

Network layer attacks

Slides from

- Dave Levin 414-spring2016

Layer 3: (Inter)network layer

- Bridges multiple “subnets” to provide *end-to-end* [internet](#) connectivity between [nodes](#)
- Provides **global** addressing (IP addresses)
- Only provides **best-effort** delivery of data (i.e., no retransmissions, etc.)
- Works across different link technologies

IP packet “header”

IP Packet Header Fields (1)

- **Version number** (4 bits)
 - Indicates the version of the IP protocol
 - Necessary for knowing what fields follow
 - “4” (for IPv4) or “6” (for IPv6)
- **Header length** (4 bits)
 - How many 32-bit words (rows) in the header
 - Typically 5
 - Can provide IP options, too
- **Type-of-service** (8 bits)
 - Allow packets to be treated differently based on different needs
 - Low delay for audio, high bandwidth for bulk transfer, etc.

IP Packet Header Fields (2)

- Two IP addresses
 - Source (32 bits)
 - Destination (32 bits)
- **Destination address**
 - *Unique* identifier/locator for the receiving host
 - Allows each node (end-host and router) to make forwarding decisions
- **Source address**
 - Unique identifier/locator for the sending host
 - Recipient can decide whether to accept the packet
 - Allows destination to *reply* to the source

IP: “Best effort” packet delivery

- Routers inspect destination address, determine “next hop” in the forwarding table
- Best effort = “I’ll give it a try”
 - Packets may be lost
 - Packets may be corrupted
 - Packets may be delivered out of order

Fixing these is the job of the transport layer!

Attacks on IP

4-bit Version	4-bit Header len	8-bit Type of service (TOS)	16-bit Total length (bytes)	
16-bit Identification			3-bit Flags	13-bit Fragment offset
8-bit Time-to-live (TTL)	8-bit Protocol		16-bit Header checksum	
32-bit Source IP address				
32-bit Destination IP address				
Payload				

Attacks on IP

4-bit Version	4-bit Header len	8-bit Type of service (TOS)	16-bit Total length (bytes)	
16-bit Identification			3-bit Flags	13-bit Fragment offset
8-bit Time-to-live (TTL)	8-bit Protocol		16-bit Header checksum	
32-bit Source IP address				
32-bit Destination IP address				
Payload				

Source-spoof

There is nothing in IP that enforces that your source IP address is really “yours”

Attacks on IP

4-bit Version	4-bit Header len	8-bit Type of service (TOS)	16-bit Total length (bytes)	
16-bit Identification			3-bit Flags	13-bit Fragment offset
8-bit Time-to-live (TTL)	8-bit Protocol		16-bit Header checksum	
32-bit Source IP address				
32-bit Destination IP address				
Payload				

Source-spoof

There is nothing in IP that enforces that your source IP address is really “yours”

Eavesdrop / Tamper

IP provides no protection of the *payload* or *header*

Source-spoofing

- Why source-spoof?
 - Consider spam: send many emails from one computer
 - Easy defense: block many emails from a given (source) IP address
 - Easy countermeasure: spoof the source IP address
 - Counter-countermeasure?
- How do you know if a packet you receive has a spoofed source?

Salient network features

- Recall: The Internet operates via *destination-based routing*
- attacker: pkt (spoofed source) -> destination
destination: pkt -> spoofed source
- In other words, the response goes to the spoofed source, *not* the attacker

Defending against source-spoofing

- How do you know if a packet you receive has a spoofed source?
 - Send a challenge packet to the (possibly spoofed) source (e.g., a difficult to guess, random nonce)
 - If the recipient can answer the challenge, then likely that the source was not spoofed
- So do you have to do this with every packet??
 - Every packet should have something that's difficult to guess
 - Recall the query ID in the DNS queries! Easy to predict => Kaminsky attack

Source spoofing

- Why source-spoof?
 - Consider DoS attacks: generate as much traffic as possible to congest the victim's network
 - Easy defense: block all traffic from a given source near the edge of your network
 - Easy countermeasure: spoof the source address
- Challenges won't help here; the damage has been done by the time the packets reach the core of our network
- Ideally, detect such spoofing *near the source*

Egress filtering

- The point (router/switch) at which traffic *enters* your network is the *ingress point*
- The point (router/switch) at which traffic *leaves* your network is the *egress point*
- You don't know who owns all IP addresses in the world, but you *do* know who in *your own network* gets what IP addresses
 - If you see a packet with a source IP address that doesn't belong to your network trying to cross your egress point, then *drop it*

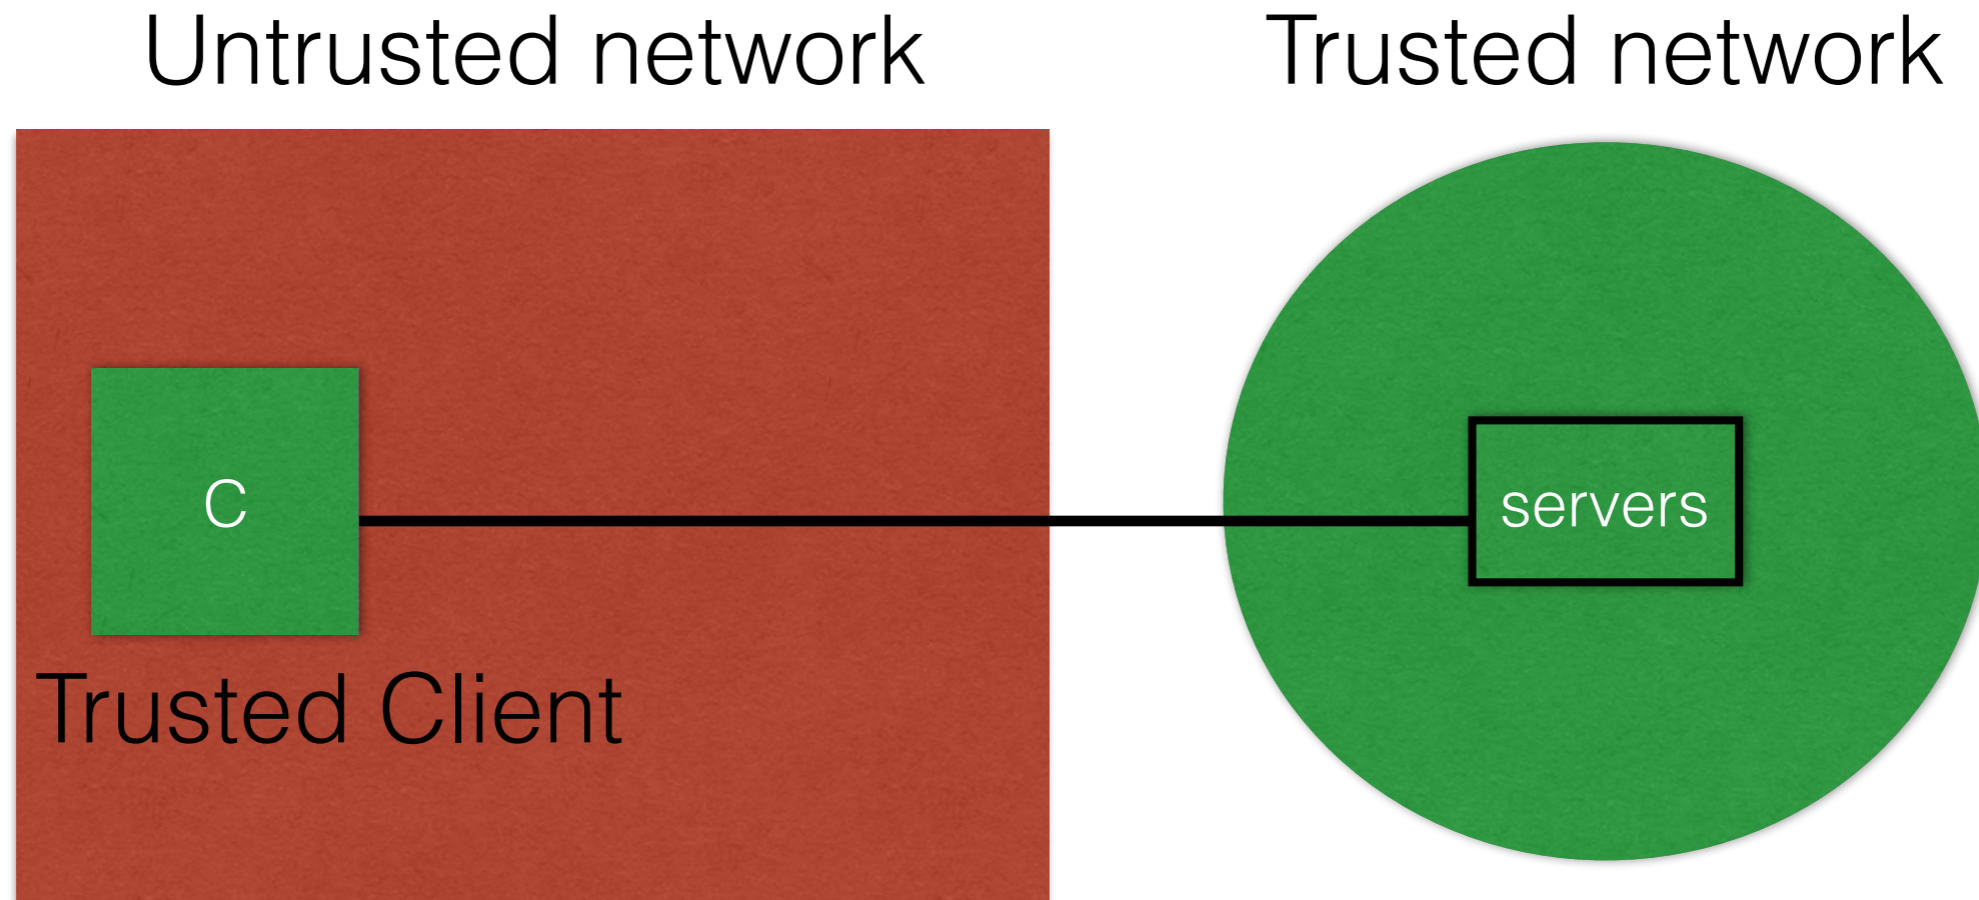

Egress filtering is not widely deployed

Eavesdropping / Tampering

4-bit Version	4-bit Header len	8-bit Type of service (TOS)	16-bit Total length (bytes)	
16-bit Identification			3-bit Flags	13-bit Fragment offset
8-bit Time-to-live (TTL)	8-bit Protocol		16-bit Header checksum	
32-bit Source IP address				
32-bit Destination IP address				
Payload				

- No security built into IP
- => Deploy secure IP *over IP*

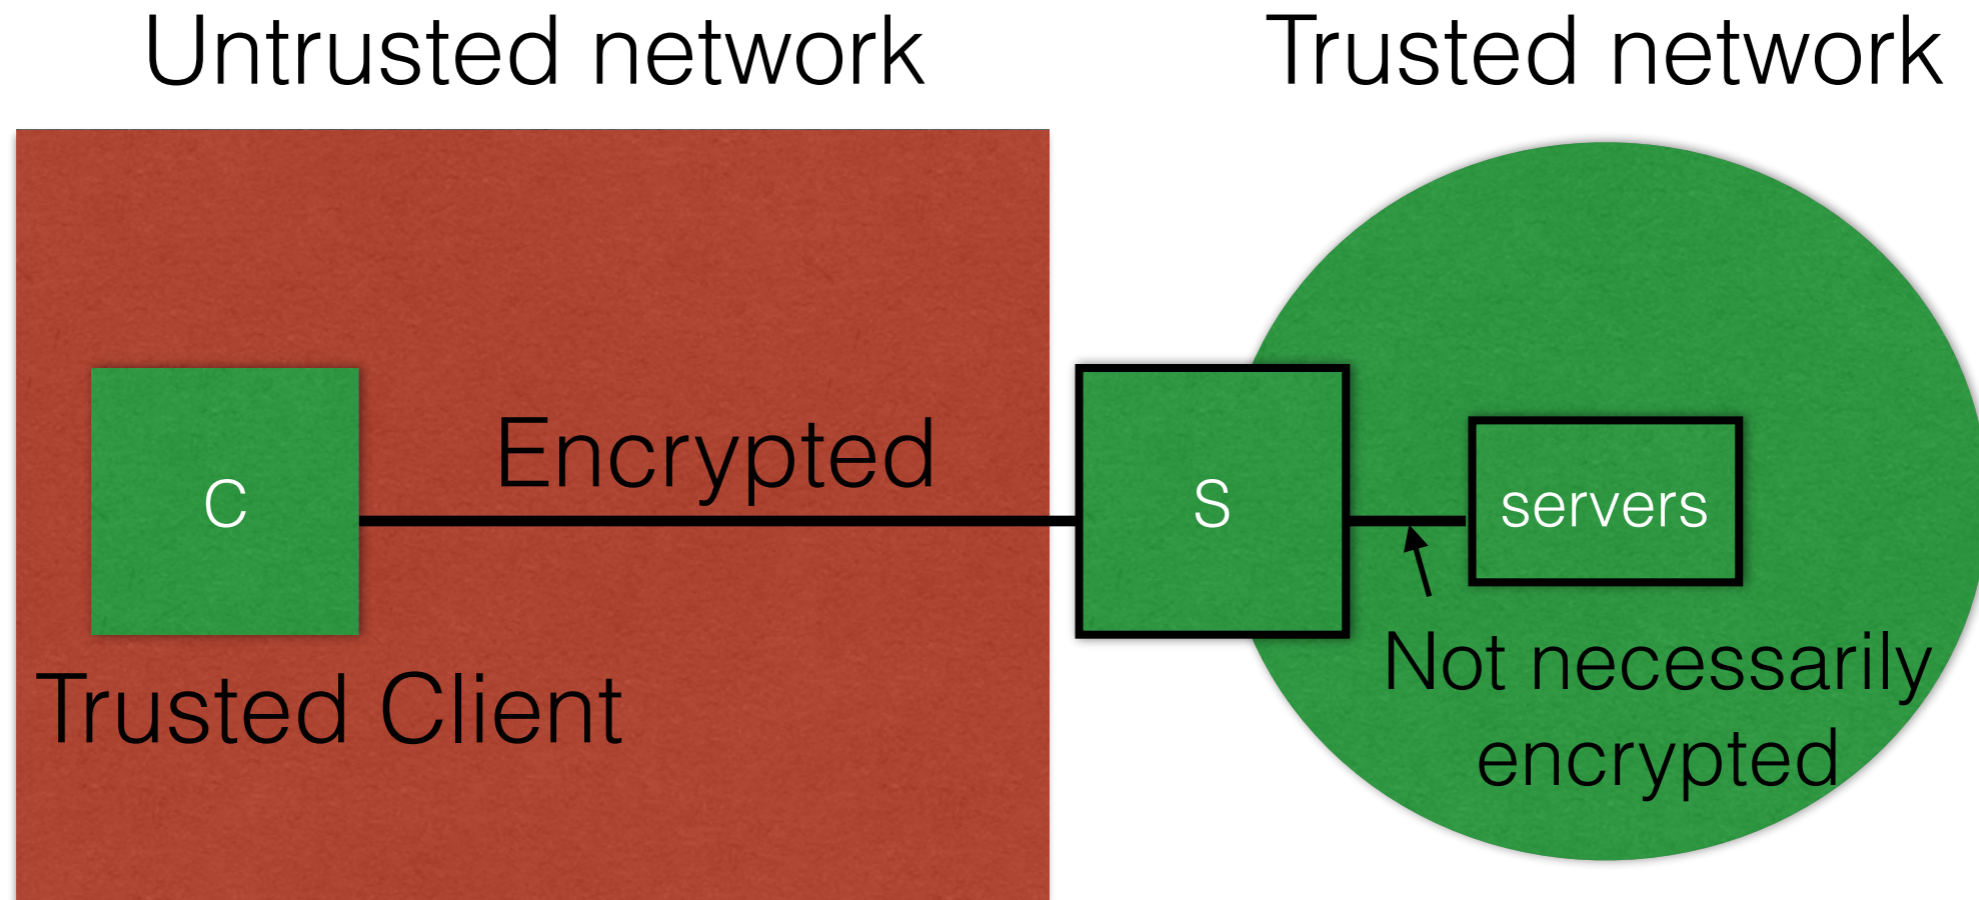

Virtual Private Networks (VPNs)

Goal: Allow the client to connect to the trusted network from within an untrusted network

Example: Connect to your company's network (for payroll, file access, etc.) while visiting a competitor's office

Virtual Private Networks (VPNs)

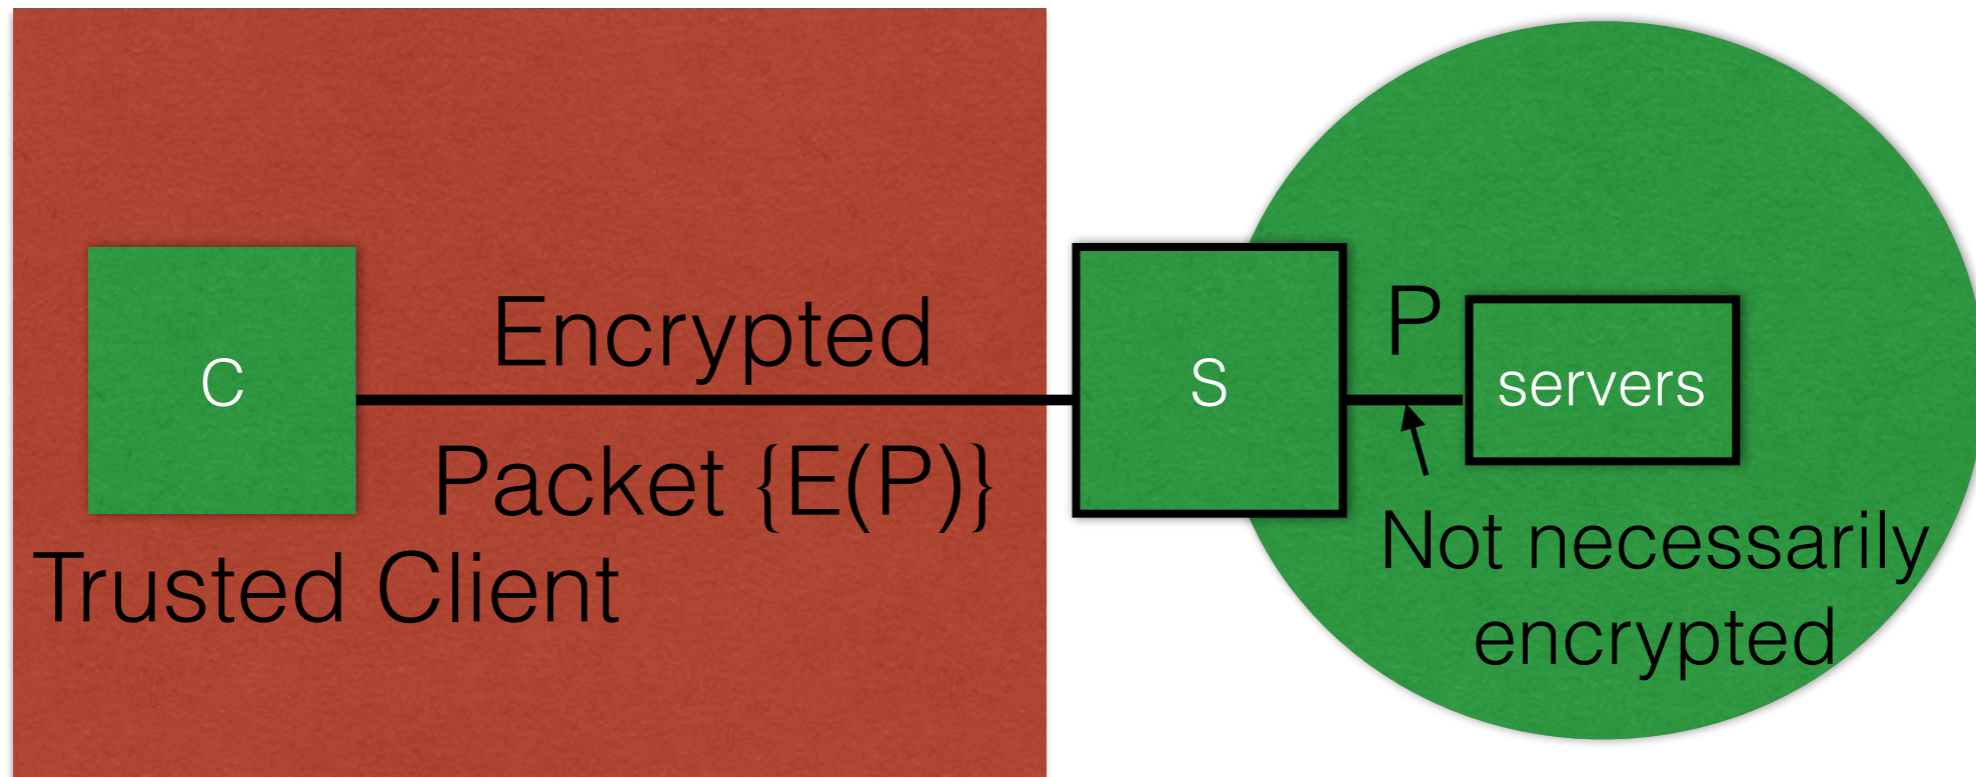

Idea: A VPN "client" and "server" together create end-to-end encryption/authentication

Predominate way of doing this: IPSec

IPSec

- Operates in a few different modes
 - Transport mode: Simply encrypt the payload but not the headers
 - Tunnel mode: Encrypt the payload *and* the headers
- But how do you encrypt the headers? How does routing work?
 - Encrypt the entire IP packet and make that the payload of another IP packet

Tunnel mode

The VPN server decrypts and then sends the payload (itself a full IP packet) as if it had just received it from the network

From the client/servers' perspective:

Looks like the client is physically connected to the network!
