Traits in Rust

Traits Overview

- **Traits** allow us to abstract behavior that types can have in common
 - In situations where we use **generic type parameters**, we can use **trait bounds** to specify that the **generic type must implement a trait**
- Traits are a bit like **Java interfaces**
 - But we can **implement traits over any type**, anywhere in the code, not only at the point we define the type

Defining a Trait

- Here is a trait with a single function

```
pub trait Summarizable {  
    fn summary(&self) -> String;  
}
```

- Specify `&self` for “instance” methods
 - Note: can also specify “associated” methods
 - Like `static` methods in Java
- Equivalent in Java:

```
public interface Summarizable {  
    String summary();  
}
```

Implementing a Trait on a Type

name of trait

type on which we are
implementing it

```
impl Summarizable for (i32, i32) {  
    fn summary(&self) -> String {  
        let &(x, y) = self;  
        format!("{}", x+y) }  
    }  
}  
  
fn foo() {  
    let y = (1, 2).summary(); // "3"  
    let z = (1, 2, 3).summary(); // fails  
}
```

trait method body

trait method invocation

Default Implementations

- Here is a trait with a default implementation

```
pub trait Summarizable {  
    fn summary(&self) -> String {  
        String::from("none")  
    }  
}
```

} default impl
Impl uses default

```
impl Summarizable for (i32, i32, i32) {}  
fn foo() {  
    let y = (1, 2).summary(); // "3"  
    let z = (1, 2, 3).summary(); // "none"  
}
```

Trait Bounds

- With generics, you can specify that a type variable must implement a trait

```
pub fn notify<T: Summarizable>(item: T) {  
    println!("Breaking news! {}",  
            item.summary());  
}
```

- This method works on any type **T** that implements the **Summarizable** trait
- Can specify multiple Trait Bounds using **+**

```
fn foo<T:Clone + Summarizable>(…) -> i32 {…}    or  
fn foo<T>(…) -> i32 where T:Clone + Summarizable {…}
```

Standard Traits

- We have seen several standard traits already
 - **Clone** holds if the object has a clone() method
 - **Copy** holds if you can copy it
 - I.e., it's a primitive
 - **Deref** holds if you can dereference it
 - I.e., it's a reference
- There are other useful ones too
 - **Display** if it can be converted to a string
 - **PartialOrd** if it implements a comparison operator

Putting all Together

- Finds the largest element in an array slice
 - Generic in the type **T** of the contents of the array

```
fn largest<T: PartialOrd + Copy>(list: &[T]) -> T
{
    let mut largest = list[0];
    for &item in list.iter() {
        if item > largest {
            largest = item;
        }
    }
    largest
}
```

Requires **Copy** trait

Requires **PartialOrd** trait

Putting all Together

- Finds the largest element in an array slice
 - Generic in the type **T** of the contents of the array

```
fn largest<T: PartialOrd + Copy>(list: &[T]) -> T
{...}
fn main() {
    let number_list = vec![34, 50, 25, 100, 65];
    let result = largest(&number_list);
    println!("The largest number is {}", result);
    let char_list = vec!['y', 'm', 'a', 'q'];
    let result = largest(&char_list);
    println!("The largest char is {}", result);
}
```

prints **The largest number is 100**

The largest char is y

Notes

- Trait implementations can be generic too

```
pub trait Queue<T> {  
    fn enqueue(&mut self, ele: T) -> (); ...  
}  
  
impl <T> Queue<T> for Vec<T> {  
    fn enqueue(&mut self, ele:T) -> () {...} ...  
}
```

- Generic method implementations of structs and enums can include trait bounds
