CMSC 330: Organization of Programming Languages

Parsing

Recall: Front End Scanner and Parser

- Scanner / lexer / tokenizer converts program source into tokens (keywords, variable names, operators, numbers, etc.) with regular expressions
- Parser converts tokens into an AST (abstract syntax tree) based on a context free grammar

Scanning ("tokenizing")

- Converts textual input into a stream of tokens
 - These are the terminals in the parser's CFG
 - Example tokens are keywords, identifiers, numbers, punctuation, etc.
- Tokens determined with regular expressions
 - Identifiers match regexp [a-zA-Z_][a-zA-Z0-9_]*
 - Non-negative integers match [0-9]+
 - Etc.
- Scanner typically ignores/eliminates whitespace

A Scanner in OCaml

```
Tok Num of char
 | Tok Sum
                                                    Tok Sum;
 | Tok END
                                                    Tok END]
let tokenize (s:string) = ...
   (* returns token list *)
;;
              let re num = Str.regexp "[0-9]" (* single digit *)
              let re add = Str.regexp "+"
              let tokenize str =
               let rec tok pos s =
                 if pos >= String.length s then
                   [Tok END]
                 else
                   if (Str.string match re num s pos) then
                    let token = Str.matched string s in
                       (Tok Num token.[0])::(tok (pos+1) s)
                   else if (Str.string match re add s pos) then
                     Tok Sum::(tok (pos+1) s)
                   else
                    raise (IllegalExpression "tokenize")
               in
               tok 0 str
```

```
tokenize "1+2" =
  [Tok_Num '1';
  Tok_Sum;
  Tok_Num '2';
  Tok_END]
```

Uses Str
library
module
for
regexps

type token =

Implementing Parsers

- Many efficient techniques for parsing
 - LL(k), SLR(k), LR(k), LALR(k)...
 - Take CMSC 430 for more details
- One simple technique: recursive descent parsing
 - This is a top-down parsing algorithm
- Other algorithms are bottom-up

Top-Down Parsing (Intuition)

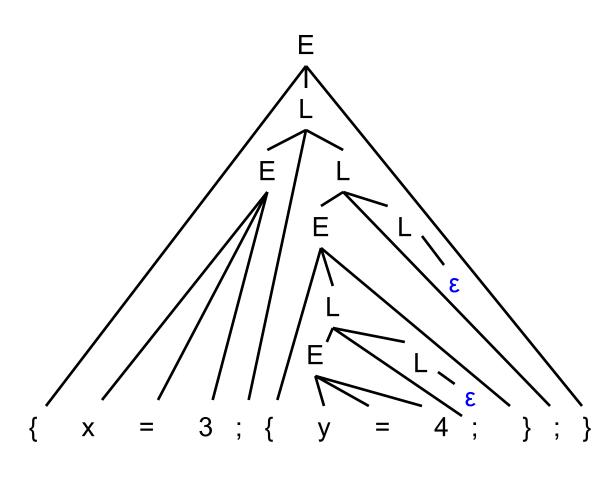

$$E \rightarrow id = n \mid \{L\}$$

 $L \rightarrow E ; L \mid \epsilon$

(Assume: id is variable name, n is integer)

Show parse tree for

$$\{x = 3; \{y = 4; \}; \}$$

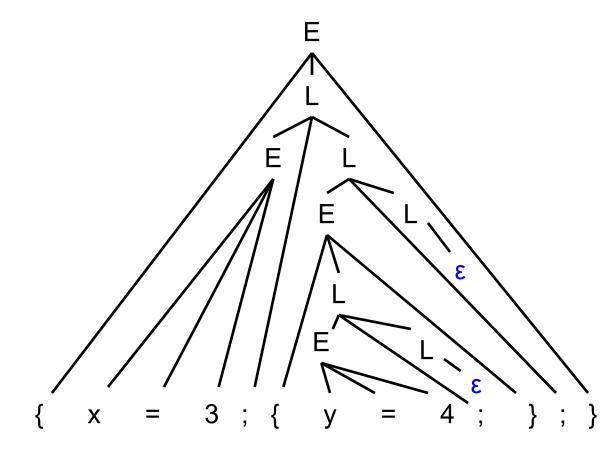

Bottom-up Parsing (Intuition)

```
E \rightarrow id = n \mid \{L\}
 L \rightarrow E ; L \mid \epsilon
```

Show parse tree for { x = 3; { y = 4; }; }

Note that final trees
constructed are same
as for top-down; only
order in which nodes
are added to tree is
different

BU Example: Shift-Reduce Parsing

- Replaces RHS of production with LHS (nonterminal)
- Example grammar
 - $S \rightarrow aA, A \rightarrow Bc, B \rightarrow b$
- Example parse
 - $abc \Rightarrow aBc \Rightarrow aA \Rightarrow S$
 - Derivation happens in reverse
- Complicated to use; requires tool support
 - Bison, yacc produce shift-reduce parsers from CFGs

Tradeoffs

- Recursive descent parsers
 - Easy to write
 - > The formal definition is a little clunky, but if you follow the code then it's almost what you might have done if you weren't told about grammars formally
 - Fast
 - > Can be implemented with a simple table
- Shift-reduce parsers handle more grammars
 - Error messages may be confusing
- Most languages use hacked parsers (!)
 - Strange combination of the two

Recursive Descent Parsing

Goal

- Can we "parse" a string does it match our grammar?
 - We will talk about constructing an AST later
- Approach: Perform parse
 - Replace each non-terminal A by the rhs of a production
 A→ rhs
 - And/or match each terminal against token in input
 - Repeat until input consumed, or failure

Recursive Descent Parsing (cont.)

- At each step, we'll keep track of two facts
 - What grammar element are we trying to match/expand?
 - What is the lookahead (next token of the input string)?
- At each step, apply one of three possible cases
 - If we're trying to match a terminal
 - If the lookahead is that token, then succeed, advance the lookahead, and continue
 - If we're trying to match a nonterminal
 - Pick which production to apply based on the lookahead

Otherwise fail with a parsing error

Parsing Example

```
E \rightarrow id = n \mid \{L\}
 L \rightarrow E ; L \mid \epsilon
```

Here n is an integer and id is an identifier

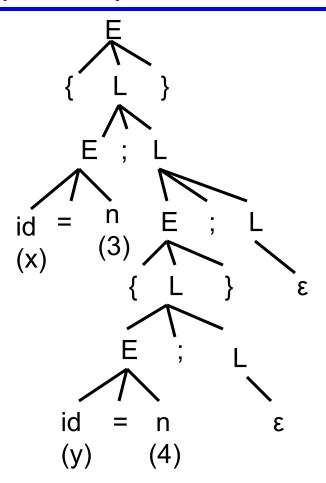

One input might be

```
• \{x = 3; \{y = 4; \}; \}
```

This would get turned into a list of tokens{ x = 3 ; { y = 4 ; } ; }

And we want to turn it into a parse tree

Parsing Example (cont.)

Recursive Descent Parsing (cont.)

- Key step: Choosing the right production
- Two approaches
 - Backtracking
 - Choose some production
 - If fails, try different production
 - Parse fails if all choices fail
 - Predictive parsing (what we will do)
 - Analyze grammar to find FIRST sets for productions
 - Compare with lookahead to decide which production to select
 - Parse fails if lookahead does not match FIRST

Selecting a Production

Motivating example

- If grammar S → xyz | abc and lookahead is x
 - Select S → xyz since 1st terminal in RHS matches x
- If grammar $S \rightarrow A \mid B \quad A \rightarrow x \mid y \mid B \rightarrow z$
 - If lookahead is x, select S → A, since A can derive string beginning with x

In general

- Choose a production that can derive a sentential form beginning with the lookahead
- Need to know what terminal may be first in any sentential form derived from a nonterminal / production

First Sets

Definition

- First(γ), for any terminal or nonterminal γ, is the set of initial terminals of all strings that γ may expand to
- We'll use this to decide which production to apply
- Example: Given grammar

```
S \rightarrow A \mid B

A \rightarrow x \mid y

B \rightarrow z
```

- First(A) = { x, y } since First(x) = { x }, First(y) = { y }
- First(B) = { z } since First(z) = { z }
- So: If we are parsing S and see x or y, we choose S → A; if we see z we choose S → B

Calculating First(γ)

- For a terminal a
 - First(a) = { a }
- For a nonterminal N
 - If $N \to \varepsilon$, then add ε to First(N)
 - If $N \to \alpha_1 \alpha_2 \dots \alpha_n$, then (note the α_i are all the symbols on the right side of one single production):
 - > Add First($\alpha_1 \alpha_2 \dots \alpha_n$) to First(N), where First($\alpha_1 \alpha_2 \dots \alpha_n$) is defined as
 - First(α_1) if $\epsilon \notin First(\alpha_1)$
 - Otherwise $(First(\alpha_1) \varepsilon) \cup First(\alpha_2 \dots \alpha_n)$
 - ightarrow If $\epsilon \in First(\alpha_i)$ for all i, $1 \le i \le k$, then add ϵ to First(N)

First() Examples

```
E \rightarrow id = n \mid \{L\}
L \rightarrow E ; L \mid \varepsilon
First(id) = { id }
First("=") = { "=" }
First(n) = { n }
First("{")= { "{" }
First("}")= { "}" }
First(";")= { ";" }
First(E) = { id, "{" }
First(L) = \{ id, "\{", \epsilon \} \}
```

```
E \rightarrow id = n | \{L\} | \epsilon
L \rightarrow E ; L
First(id) = { id }
First("=") = { "=" }
First(n) = { n }
First("{")= { "{" }
First("}")= { "}" }
First(";")= { ";" }
First(E) = \{ id, "\{", \epsilon \} \}
First(L) = { id, "{", ";" }
```

Given the following grammar:

What is First(S)?

Given the following grammar:

What is First(S)?

A. {a}

```
S -> aAB
A -> CBC
B -> b
C -> cC | \epsilon
```

Given the following grammar:

What is First(B)?

```
A. {a}
B. {b,c}
C. {b}
D. {c}
```

Given the following grammar:

What is First(B)?

```
A. {a}B. {b,c}C. {b}D. {c}
```

Given the following grammar:

What is First(A)?

```
A. {a}
B. {b,c}
C. {b}
D. {c}
```

```
S -> aAB
A -> CBC
B -> b
C -> cC | \varepsilon
```

Given the following grammar:

What is First(A)?

```
A. {a}
B. {b,c}
C. {b}
D. {c}
```

```
Note:
First(B) = {b}
First(C) = {c, \epsilon}
```

Recursive Descent Parser Implementation

- For all terminals, use function match_tok a
 - If lookahead is a it consumes the lookahead by advancing the lookahead to the next token, and returns
 - Fails with a parse error if lookahead is not a
- For each nonterminal N, create a function parse_N
 - Called when we're trying to parse a part of the input which corresponds to (or can be derived from) N
 - parse_S for the start symbol S begins the parse

match_tok in OCaml

```
let tok list = ref [] (* list of parsed tokens *)
exception ParseError of string
let match tok a =
 match !tok list with
    (* checks lookahead; advances on match *)
    | (h::t)  when a = h \rightarrow tok  list := t
    | -> raise (ParseError "bad match")
(* used by parse X *)
let lookahead () =
 match !tok list with
    [] -> raise (ParseError "no tokens")
  | (h::t) -> h
```

Parsing Nonterminals

- The body of parse_N for a nonterminal N does the following
 - Let $N \to \beta_1 \mid ... \mid \beta_k$ be the productions of N
 - \triangleright Here β_i is the entire right side of a production- a sequence of terminals and nonterminals
 - Pick the production N → β_i such that the lookahead is in First(β_i)
 - ▶ It must be that $First(β_i) \cap First(β_i) = \emptyset$ for $i \neq j$
 - \triangleright If there is no such production, but $N \rightarrow \epsilon$ then return
 - Otherwise fail with a parse error
 - Suppose $\beta_i = \alpha_1 \ \alpha_2 \ ... \ \alpha_n$. Then call parse_ $\alpha_1()$; ...; parse_ $\alpha_n()$ to match the expected right-hand side, and return

Example Parser

- ▶ Given grammar S → xyz | abc
 - First(xyz) = { x }, First(abc) = { a }
- Parser

```
let parse S () =
  if lookahead () = "x" then (* S → xyz *)
    (match tok "x";
     match tok "y";
     match tok "z")
   else if lookahead () = "a" then (* S \rightarrow abc *)
     (match tok "a";
     match tok "b";
     match tok "c")
   else raise (ParseError "parse S")
```

Another Example Parser

▶ Given grammar $S \rightarrow A \mid B \quad A \rightarrow x \mid y \quad B \rightarrow z$

```
First(A) = { x, y }, First(B) = { z }
```

Parser:

let rec parse_S () =

If lookahead () = "x" ||

lookahead () = "y" th

parse_A () (* S → A *)

recursive
functions in

let rec parse_S () =

lookahead () = "x" ||

lookahead () = "y" th

parse_B () (* S → B *)

else raise (ParseFrror "

parse_S and
parse_A and
parse_B can

OCaml -

each call the other

```
lookahead () = "y" then
    parse A () (* S \rightarrow A *)
  else if lookahead () = "z" then
    parse B () (* S \rightarrow B *)
  else raise (ParseError "parse S")
and parse A () =
  if lookahead () = "x" then
    match tok "x" (* A \rightarrow x *)
  else if lookahead () = "y" then
    match tok "y" (* A \rightarrow y *)
  else raise (ParseError "parse A")
and parse B () = ...
```

Example

```
E \rightarrow id = n \mid \{L\}
 L \rightarrow E ; L \mid \epsilon
```

```
First(E) = { id, "{" }
```

Parser:

```
let rec parse_E () =
  if lookahead () = "id" then
    (* E → id = n *)
    (match_tok "id";
    match_tok "=";
    match_tok "n")

else if lookahead () = "{" then
    (* E → { L } *)
    (match_tok "{";
    parse_L ();
    match_tok "}")

else raise (ParseError "parse_A")
```

```
and parse_L () =
  if lookahead () = "id"
  || lookahead () = "{" then
      (* L → E ; L *)
      (parse_E ();
      match_tok ";";
      parse_L ())
  else
      (* L → ε *)
      ()
```

Things to Notice

- If you draw the execution trace of the parser
 - You get the parse tree (we'll consider ASTs later)
- Examples
 - Grammar

$$S \rightarrow xyz$$

 $S \rightarrow abc$

• String "xyz"

```
parse_S ()

match_tok "x"

match_tok "y"

x y z

match_tok "z"
```

Grammar

$$S \rightarrow A \mid B$$

 $A \rightarrow x \mid y$
 $B \rightarrow z$

Things to Notice (cont.)

- This is a predictive parser
 - Because the lookahead determines exactly which production to use
- This parsing strategy may fail on some grammars
 - Production First sets overlap
 - Production First sets contain ε
 - Possible infinite recursion
- Does not mean grammar is not usable
 - Just means this parsing method not powerful enough
 - May be able to change grammar

Conflicting First Sets

- Consider parsing the grammar E → ab | ac
 - First(ab) = a

Parser cannot choose between

• First(ac) = a

RHS based on lookahead!

- ▶ Parser fails whenever $A \rightarrow \alpha_1 \mid \alpha_2$ and
 - First(α_1) \cap First(α_2) != ϵ or \emptyset
- Solution
 - Rewrite grammar using left factoring

Left Factoring Algorithm

- Given grammar
 - $A \rightarrow x\alpha_1 | x\alpha_2 | ... | x\alpha_n | \beta$
- Rewrite grammar as
 - $A \rightarrow xL \mid \beta$
 - L $\rightarrow \alpha_1 \mid \alpha_2 \mid \dots \mid \alpha_n$
- Repeat as necessary
- Examples
 - $S \rightarrow ab \mid ac$ $\Rightarrow S \rightarrow aL$ $L \rightarrow b \mid c$
 - S \rightarrow abcA | abB | a \Rightarrow S \rightarrow aL L \rightarrow bcA | bB | ϵ
 - L \rightarrow bcA | bB | ϵ \Rightarrow L \rightarrow bL' | ϵ L' \rightarrow cA | B

Alternative Approach

- Change structure of parser
 - First match common prefix of productions
 - Then use lookahead to chose between productions
- Example
 - Consider parsing the grammar E → a+b | a*b | a

```
let parse_E () =
  match_tok "a"; (* common prefix *)

if lookahead () = "+" then (* E → a+b *)
      (match_tok "+";
      match_tok "b")

else if lookahead () = "*" then (* E → a*b *)
      (match_tok "*";
      match_tok "b")

else () (* E → a *)
```

Left Recursion

- Consider grammar S → Sa | ε
 - Try writing parser

```
let rec parse_S () =
  if lookahead () = "a" then
     (parse_S ();
    match_tok "a") (* S → Sa *)
  else ()
```

- Body of parse_S () has an infinite loop!
 - > Infinite loop occurs in grammar with left recursion

Right Recursion

- ► Consider grammar $S \rightarrow aS \mid \epsilon$ Again, First(aS) = a
 - Try writing parser

- Will parse_S() infinite loop?
 - Invoking match_tok will advance lookahead, eventually stop
- Top down parsers handles grammar w/ right recursion

Algorithm To Eliminate Left Recursion

- Given grammar
 - $A \rightarrow A\alpha_1 \mid A\alpha_2 \mid ... \mid A\alpha_n \mid \beta$ • β must exist or no derivation will yield a string
- Rewrite grammar as (repeat as needed)
 - $A \rightarrow \beta L$
 - $L \rightarrow \alpha_1 L \mid \alpha_2 L \mid ... \mid \alpha_n L \mid \epsilon$
- Replaces left recursion with right recursion
- Examples

•
$$S \rightarrow Sa \mid \epsilon$$
 $\Rightarrow S \rightarrow L$ $L \rightarrow aL \mid \epsilon$ • $S \rightarrow Sa \mid Sb \mid c$ $\Rightarrow S \rightarrow cL$ $L \rightarrow aL \mid bL \mid \epsilon$

CMSC 330 Summer 2020

What Does the following code parse?

```
let parse_S () =
  if lookahead () = "a" then
      (match_tok "a";
      match_tok "x";
      match_tok "y")
  else if lookahead () = "q" then
      match_tok "q"
  else
    raise (ParseError "parse_S")
```

```
A. S -> axyqB. S -> a | qC. S -> aaxy | qqD. S -> axy | q
```

What Does the following code parse?

```
let parse_S () =
  if lookahead () = "a" then
      (match_tok "a";
      match_tok "x";
      match_tok "y")
  else if lookahead () = "q" then
      match_tok "q"
  else
    raise (ParseError "parse_S")
```

```
A. S -> axyq
B. S -> a | q
C. S -> aaxy | qq
D. S -> axy | q
```

What Does the following code parse?

```
let rec parse_S () =
  if lookahead () = "a" then
      (match_tok "a";
      parse_S ())
  else if lookahead () = "q" then
      (match_tok "q";
      match_tok "p")
  else
    raise (ParseError "parse_S")
```

```
A. S -> aS | qpB. S -> a | S | qpC. S -> aqSpD. S -> a | q
```

What Does the following code parse?

```
let rec parse_S () =
  if lookahead () = "a" then
      (match_tok "a";
      parse_S ())
  else if lookahead () = "q" then
      (match_tok "q";
      match_tok "p")
  else
    raise (ParseError "parse_S")
```

```
A. S -> aS | qpB. S -> a | S | qpC. S -> aqSpD. S -> a | q
```

Can recursive descent parse this grammar?

- A. Yes
- B. No

Can recursive descent parse this grammar?

- A. Yes
- B. No

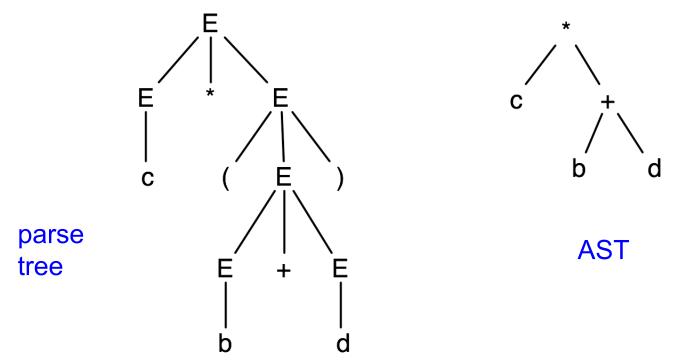

(due to left recursion)

What's Wrong With Parse Trees?

- Parse trees contain too much information
 - Example
 - > Parentheses
 - > Extra nonterminals for precedence
 - This extra stuff is needed for parsing
- But when we want to reason about languages
 - Extra information gets in the way (too much detail)

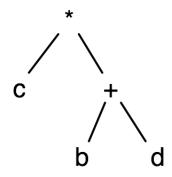

Abstract Syntax Trees (ASTs)

An abstract syntax tree is a more compact, abstract representation of a parse tree, with only the essential parts

Abstract Syntax Trees (cont.)

- Intuitively, ASTs correspond to the data structure you'd use to represent strings in the language
 - Note that grammars describe trees
 - > So do OCaml datatypes, as we have seen already
 - E → a | b | c | E+E | E-E | E*E | (E)

Producing an AST

- To produce an AST, we can modify the parse() functions to construct the AST along the way
 - match_tok a returns an AST node (leaf) for a
 - parse_A returns an AST node for A
 - > AST nodes for RHS of production become children of LHS node
- Example
 - $S \rightarrow aA$

```
let rec parse_S () =
   if lookahead () = "a" then
      let n1 = match_tok "a" in
      let n2 = parse_A () in
      Node(n1,n2)
   else raise ParseError "parse_S"
```

The Compilation Process
