

AVL Trees Vs. Heaps

Note Title

11/13/2007

Can we use an AVL tree to sort?

(A thought question.)

Building AVL Tree: $O(n \log n)$

In-Order Traversal: $O(n)$

- Huh? It takes $O(n)$ to build a heap, but $O(n \log n)$ to build an AVL tree. Why?

- What is the key difference between Heap + AVL?

We care about hierarchical ordering. (Relative Ordering of siblings doesn't matter!!)

We care about relative ordering of siblings.

If we built a decision tree to describe BuildAVLTree, it would have leaves that were all possible permutations of the input.

How many leaves?

$$3! = 3 \cdot 2 \cdot 1 = 6$$

- There are $n!$ leaf nodes
- The path length is $\log(n!)$
- So the lower bound for work to build an AVL tree is $O(\log n!)$
- We learned that this is $O(n \log n)$.
- So AVL Search $\in O(\underbrace{n \log n}_{\text{Build AVL}} + \underbrace{n}_{\text{Inorder traversal}}) \in O(n \log n)$
